

1 **Supplementary Information**

2 **Modern ENSO $\delta^{18}\text{O}_{\text{precip}}$ Signals**

3 While we incorporate over 10,000 separate weekly measurements of isotopes in
4 precipitation in our analysis of modern ENSO signals, the time interval of observations is
5 only 6 years and does not include large El Niño events such as took place in 1997-8. In
6 order to validate these observed signals as features of ENSO teleconnections, we analyze
7 model output of $\delta^{18}\text{O}$ from the Stable Water Isotope Intercomparison Group (SWING)
8 publically available on their website ([http://atoc.colorado.edu/~dcn/SWING/datab-](http://atoc.colorado.edu/~dcn/SWING/database.php)
9 [ase.php](http://atoc.colorado.edu/~dcn/SWING/database.php)). We use data from the Echem4 results of the S1b Experiment in which the
10 model is forced with varying SST from the HadISST data set.

11 Seasonal correlation coefficients between $\delta^{18}\text{O}_{\text{precip}}$ and the Niño 3.4 Index from 1950-
12 2003 that are statistically significant at the 95% confidence interval are shown in SFIG 1.
13 In the winter (JFM), negative correlations extend across the Pacific Northwest, Gulf
14 Coast, and East Coast. These correlations match observed signals in the Pacific
15 Northwest and East Coast. The modeled isotopic change, however, is significantly
16 stronger surrounding the Gulf Coast including the Great Plains and is concentrated farther
17 north on the West Coast as compared to observations. In the spring (AMJ), the model
18 shows strong positive correlation in the Southwest, in good agreement with observations.
19 Also similar to observations, the model shows little significant correlation across the US
20 during the summer (JAS). Finally, in the fall (OND), negative correlation is modeled
21 around the Gulf Coast area. This negative correlation extends west into the Great Plains
22 including the Meade, KS locality, though this signal is only significant at the 88%
23 confidence interval (not shown). Modeled results do not show the strong negative signal
24 observed in the Southwest during the fall.

25 While there are some discrepancies between observed and modeled signals, there is very
26 good agreement on the isotopic changes relevant to our discussion based on seasonality
27 of carbonate formation at each locality (see discussion in main text). Therefore, we
28 regard the isotopic anomalies observed in modern precipitation used in our analysis to be
29 a robust feature of modern ENSO teleconnections.
