14 **Abstract.** Holocene centennial-scale paleoenvironmental variability has been described in a
15 multiproxy analysis (i.e. lithology, geochemistry, macrofossil and microfossil analyses) of a
16 paleoecological record from the Padul basin in Sierra Nevada, southern Iberian Peninsula. This
17 sequence covers a relevant time interval hitherto unreported in the studies of the Padul
18 sedimentary sequence. The ca. 4700 yr-long record has preserved proxies of climate variability,
19 with vegetation, lake levels and sedimentological change the Holocene in one of the most unique
20 and southernmost peat bogs from Europe. The progressive Middle and Late Holocene trend
21 toward arid conditions identified by numerous authors in the western Mediterranean region,
22 mostly related to a decrease in summer insolation, is also documented in this record, being here
23 also superimposed by centennial-scale variability in humidity. In turn, this record shows
24 centennial-scale climate oscillations in temperature that correlate with well-known climatic
25 events during the Late Holocene in the western Mediterranean region, synchronous with
26 variability in solar and atmospheric dynamics. The multiproxy Padul record first shows a
27 transition from a relatively humid Middle Holocene in the western Mediterranean region to more
28 aridity from ~4700 to ~2800 cal yr BP. A relatively warm and humid period occurred between
29 ~2600 to ~1600 cal yr BP, coinciding with persistent negative NAO conditions and the historic
30 Iberian-Roman Humid Period. Enhanced arid conditions, co-occurring with overall positive
31 NAO conditions and increasing solar activity, are observed between ~1550 to ~450 cal yr BP
32 (~400 to ~1400 CE) and colder and warmer conditions happened during the Dark Ages and
33 Medieval Climate Anomaly, respectively. Slightly wetter conditions took place during the end of
34 the MCA and the first part of the Little Ice Age, which could be related to a change towards
35 negative NAO conditions and minima in solar activity. Evidences of higher human impact in the
36 Padul peat bog area are observed in the last ~1550 cal yr BP. Time series analysis performed
37 from local (*Botryococcus* and TOC) and regional signals (Mediterranean forest) helped us
38 determining the relationship between southern Iberian climate evolution, atmospheric, oceanic
39 dynamics and solar activity.

40 **Keywords:** Holocene, Padul, peat bog, North Atlantic Oscillation, atmospheric dynamics,
41 southern Iberian Peninsula, Sierra Nevada, western Mediterranean.

42 1 Introduction

43 The Mediterranean area is situated in a sensitive region between temperate and subtropical
44 climates making it an important place to study the connections between atmospheric and oceanic
45 dynamics and environmental changes. Climate in the western Mediterranean and the southern
46 Iberian Peninsula is influenced by several atmospheric and oceanic dynamics (Alpert et al.,
47 2006), including the North Atlantic Oscillation (NAO) one of the principal atmospheric
48 phenomenon controlling climate in the area (Hurrell, 1995; Moreno et al., 2005). Recent NAO
49 reconstructions in the western Mediterranean region relate negative and positive NAO conditions
50 with an increase and decrease in winter (effective) precipitation, respectively (e.g. Olsen et al.,
51 2012; Trouet et al., 2009). Numerous paleoenvironmental studies in the western Mediterranean
52 have detected a link at millennial- and centennial-scales between the oscillations of paleoclimate
53 proxies studied in sedimentary records with solar variability and atmospheric (i.e., NAO) and/or
54 ocean dynamics during the Holocene (e.g. Fletcher et al., 2013; Moreno et al., 2012; Rodrigo-
55 Gámiz et al., 2014). Very few montane and low altitude lake records in southern Iberia document
56 centennial-scale climate change [see, for example Zoñar Lake (Martín-Puertas et al., 2008)], with
57 most terrestrial records in the western Mediterranean region evidencing only millennial-scale
58 cyclical changes. Therefore, higher-resolution decadal-scale analyses are thus necessary in order
59 to analyze the link between solar activity, atmospheric and oceanographic systems with
60 terrestrial environment in this area at shorter (ie., centennial) time scales.

61 Sediments from lakes, peat bogs and marine records from the western Mediterranean have
62 documented an aridification trend during the Late Holocene (e.g. Carrión et al., 2010b; Gil-
63 Romera et al., 2014; Jalut et al., 2009). This trend, however, was superimposed by shorter-term
64 climate variability, as shown by several recent studies from the region, as well as human pressure
65 (Carrión, 2002; Fletcher et al., 2013; Jiménez-Moreno et al., 2013; Martín-Puertas et al., 2008;
66 Ramos-Román et al., 2016). This relationship between climate variability, culture evolution and
67 human impact during the Late Holocene has also been the subject of recent paleoenvironmental
68 studies (Carrión et al., 2007; Lillios et al., 2016; López-Sáez et al., 2014; Magny, 2004).
69 However, it is still unclear what has been the main forcing driving environmental change (i.e.,
70 deforestation) in this area during this time: was it climate or humans?

71 Within the western Mediterranean region, Sierra Nevada is the highest and southernmost
72 mountain range in the Iberian Peninsula and thus presents a critical area for paleoenvironmental
73 studies. Most high-resolution studies there have come from high elevation sites. The well-known
74 Padul peat bog site is located at the western foot of the Sierra Nevadas (Fig. 1) and bears one of
75 the longest continental records in southern Europe, with a sedimentary sequence of ca. 100 m
76 thick that could represent the last 1 Ma (Ortiz et al., 2004). Several research studies, including
77 radiocarbon dating, geochemistry and pollen analyses, have been carried out on previous cores
78 from Padul, and have documented glacial/interglacial cycles during the Pleistocene and up until
79 the Middle Holocene. However, the Late Holocene section of the Padul sedimentary sequence
80 has never been retrieved and studied. This was due to the location of these previous corings
81 within the peat mine exploitation setting, where the upper (and non productive) part of the
82 sedimentary sequence was missing (Florschütz et al., 1971; Ortiz et al., 2004; Pons and Reille,
83 1988).

84 Here we present a new record from the Padul peat bog basin: Padul-15-05, a 42.64 m-long
85 sediment core that, for the first time, contains a continuous record of the Late Holocene (Fig. 2).
86 A high-resolution multi-proxy analysis of the upper 1.15 m, the past ~4700 cal yr BP, has
87 allowed us to determine a complete paleoenvironmental and paleoclimatic record at centennial-

88 and millennial-scales. To accomplish that, we reconstructed changes in the Padul peat bog
89 vegetation, ~~sedimentation~~, climate and human impact during the Holocene throughout the
90 interpretation of the lithology, palynology and geochemistry.
91 Specifically, the main objective of this paper is to determine environmental variability and
92 climate evolution in the southern Iberian Peninsula and the western Mediterranean region and
93 their linkages to northern hemisphere climate and solar variability during the Holocene. In order
94 to do this, we compared our results with other paleoclimate records from regional areas and solar
95 activity from the northern hemisphere for the past ca. 4.7 cal ka BP (Bond et al., 2001; Laskar et
96 al., 2004; Sicre et al., 2016; Steinhilber et al., 2009).

97 2 Study site

98 2.1 Regional setting: Sierra Nevada climate and vegetation

99 Sierra Nevada is a W-E aligned mountain range located in Andalusia (southern Spain). Climate
100 in this area is Mediterranean, with cool and humid winters and hot/warm summer drought. In the
101 Sierra Nevada, the mean annual temperature at approximately 2500 m asl is 4.5 °C and the mean
102 annual precipitation is 700 mm/yr (Oliva et al., 2009). Sierra Nevada is strongly influenced by
103 thermal and precipitation variations due to the altitudinal gradient (from ca. 700 to more than
104 3400 m), which control plant taxa distribution in different bioclimatic vegetation belts due to the
105 variability in thermotypes and ombrotypes (Valle Tendero, 2004). According to the
106 climatophilous series classification, Sierra Nevada is divided in four different vegetation belts
107 (Fig. 1). The crioremediterranean vegetation belt, occurring above ~2800 m, is characterized
108 principally by *Festuca clementei*, *Hormatophylla purpurea*, *Erigeron frigidus*, *Saxifraga*
109 *nevadensis*, *Viola crassiuscula*, and *Linaria glacialis*. The oromediterranean belt, between ~1900
110 to 2800 m, bears *Pinus sylvestris*, *P. nigra*, *Juniperus communis* subsp. *hemisphaerica*, *J. sabina*
111 var. *humilis*, *J. communis* subsp. *nana*, *Genista versicolor*, *Cytisus oromediterraneus*,
112 *Hormatophylla spinosa*, *Prunus prostrata*, *Deschampsia iberica* and *Astragalus sempervirens*
113 subsp. *nevadensis* as the most representative species. The supramediterranean belt, from
114 approximately 1400 to 1900 m of elevation, principally includes *Quercus pyrenaica*, *Q. faginea*,
115 *Q. rotundifolia*, *Acer opalus* subsp. *granatense*, *Fraxinus angustifolia*, *Sorbus torminalis*,
116 *Adenocarpus decorticans*, *Helleborus foetidus*, *Daphne gnidium*, *Clematis flammula*, *Cistus*
117 *laurifolius*, *Berberis hispanicus*, *Festuca scariosa*, *Thymus serpyloides* subsp. *gadorensis*,
118 *Helichrysum italicum* subsp. *serotinum*, *Santolina rosmarinifolia* subps. *canescens* and *Artemisia*
119 *glutinosa*. The mesomediterranean vegetation belt occurs between ~600 and 1400 m of elevation
120 and is characterized by *Quercus rotundifolia*, *Retama sphaerocarpa*, *Paeonia coriacea*,
121 *Juniperus oxycedrus*, *Rubia peregrina*, *Asparagus acutifolius*, *D. gnidium*, *Ulex parviflorus*,
122 *Genista umbellata*, *Cistus albidus* and *C. laurifolius* (Al Aallali et al., 1998; Valle, 2003). The
123 human impact over this area, especially important during the last millennium, affected the
124 natural vegetation distribution through fire, deforestation, cultivation. (i.e., *Olea*) and subsequent
125 reforestation (mostly *Pinus*) (Anderson et al., 2011).

126 2.2 Padul peat bog

127 The Padul basin is situated at approximately 725 m of elevation in the southeastern part of the
128 Granada Basin, at the foothill of the southwestern Sierra Nevada, Andalucía, Spain (Fig. 1). This
129 is one of the most seismically active areas in the southern Iberian Peninsula with numerous faults

130 in NW-SE direction, with the Padul fault being one of these active normal faults (Alfaro et al.,
131 2001). It is a small extensional basin approximately 12 km long and covering an area of
132 approximately 45 km², which is bounded by the Padul normal fault. The sedimentary in-filling of
133 the basin consists of Neogene and Quaternary deposits; Upper Miocene conglomerates,
134 calcarenites and marls, and Pliocene and Quaternary alluvial sediments, lacustrine and peat bog
135 deposits (Sanz de Galdeano et al., 1998; Delgado et al., 2002; Domingo et al., 1983). The Padul
136 peat bog is an endorheic area with a surface of approximately 4 km² placed in the Padul basin
137 that contains a sedimentary sequence mostly characterized by peat. The basin fill is asymmetric,
138 with thicker peat infill to the northeast (~100 m thick; Domingo-García et al., 1983; Florschütz et
139 al., 1971; Nestares and Torres, 1997) and disappearing to the southwest (Alfaro et al., 2001). The
140 main source area of the sediments in the Padul peat bog is Sierra Nevada, which is characterized
141 at higher elevations by Paleozoic siliceous metamorphic rocks (mostly mica-schists and
142 quartzites) from the Nevado-Filabride complex and, at lower elevations and acting as bedrock,
143 by Triassic dolomites, limestones and phyllites from the Alpujárride Complex (Sanz de
144 Galdeano et al. 1998). Geochemistry in the Padul sediments is influenced by detritic materials
145 coming from the neighboring mountains, mainly the Sierra Nevada mountain range (Ortiz et al.,
146 2004). In addition, groundwater inputs into the Padul basin are the main reason why there is a
147 wetland in this area. These inputs come from the Triasic carbonates aquifers (N and S edge to the
148 basin), the out-flow of the Granada Basin (W) and the conglomerate aquifer to the east edge
149 (Castillo Martín et al., 1984; Ortiz et al., 2004). The main water output is by evaporation and
150 evapotranspiration, water wells and by canals (“madres”) that drain the water to the Dúrcal river
151 to the southeast (Castillo Martín et al., 1984). Climate in the Padul area is characterized by a
152 mean annual temperature of 14.4 °C and a mean annual precipitation of 445 mm
153 (<http://www.aemet.es/>).

154 Vegetation in the Padul area is dominated by *Q. rotundifolia* (and in less amounts *Q. faginea*),
155 which is normally accompanied by *Pistacia terebinthus*. Shrub species in the area include
156 *Juniperus oxycedrus*, *Crataegus monogyna*, *Daphne gnidium* and *Ruscus aculeatus*. Creepers
157 such as *Lonicera implexa*, *Rubia peregrina*, *Hedera helix*, *Asparagus acutifolius* also occur in
158 this area and some herbs, such as *Paeonia broteroi*. *Quercus coccifera* also occurs in crests and
159 very sunny rocky outcrops. *Retama sphaerocarpa* and *Genista cinerea* subsp. *speciosa* and the
160 *Thymo-Stipetum tenacissime* series also occur in sunny areas and in more xeric soils.
161 Nitrophilous communities occur in soils disrupted by livestock, pathways or open forest,
162 normally related with anthropization (Valle, 2003).

163 The Padul-15-05 drilling site was located around 50 m south of the present-day Padul lake shore
164 area. This basin area is presently subjected to seasonal water level fluctuations and is principally
165 dominated by *Phragmites australis* (Poaceae). The lake environment is dominated by aquatic
166 and wetland communities with *Chara vulgaris*, *Myriophyllum spicatum*, *Potamogeton*
167 *pectinatus*, *Potamogetum coloratus*, *Phragmites australis*, *Typha dominguensis*, *Apium*
168 *nodiflorum*, *Juncus subnodulosus*, *Carex hispida*, *Juncus bufonius* and *Ranunculus muricatus*
169 between others (Pérez Raya and López Nieto, 1991). Some sparse riparian trees occur in the
170 northern lake shore, such as *Populus alba*, *Populus nigra*, *Salix* sp., *Ulmus minor* and *Tamarix*.

171 3 Material and methods

172 Two sediment cores, Padul-13-01 (37°00'40"N; 3°36'13"W) and Padul-15-05 (37°00'39.77"N;
173 3°36'14.06"W) with a length of 58.7 cm and 42.64 m, respectively, were collected between
174 2013 and 2015 from the peat bog (Fig. 1). The cores were taken using a Rolatec RL-48-L drilling

175 machine equipped with a hydraulic piston corer from the Scientific Instrumentation Centre of the
176 University of Granada. The sediment cores were wrapped in film, put in core boxes, transported
177 and stored in a dark cool room at +4°C.

178 **3.1 Age-depth model (AMS radiocarbon dating)**

179 The core chronology was constrained using fourteen AMS radiocarbon dates from plant remains
180 and organic bulk samples taken throughout the cores (Table 1). In addition, one sample with
181 gastropods was also measured for AMS radiocarbon analysis, although it was rejected due to
182 important reservoir effect, which provide a very old date. Thirteen of these samples came from
183 Padul-15-05 and one from the nearby Padul-13-01 (Table 1). We were able to use this date from
184 Padul-13-01 core as there is a very significant correlation between the upper part of Padul-15-05
185 and Padul-13-01 cores, shown by identical lithological and geochemical changes (Supplementary
186 information 1; Figure S1). The age model for the upper ~3 m ~~until 21 cm from the surface~~ was
187 built using the R-code package ‘Clam 2.2’ (Blaauw, 2010) employing the calibration curve
188 IntCal 13 (Reimer et al., 2013), a 95 % of confidence range, a smooth spline (type 4) with a 0.20
189 smoothing value and 1000 iterations (Fig. 2). The chronology of the uppermost 21 cm of the
190 record was built using a linear interpolation between the last radiocarbon date and the top of the
191 record (Present; 2015 CE). The studied interval in the present work are the uppermost 115 cm of
192 the record that are constrained by six AMS radiocarbon dates (Fig. 2).

193 **3.2 Lithology, MS, XRF and TOC**

194 The length for the Padul-15-05 core is ~ 43 m. In this study, we focus in the uppermost ~ 115 cm
195 from that core. Padul-15-05 core was split longitudinally and was described in the laboratory
196 with respect to lithology and color (Fig. 3).

197 Magnetic susceptibility (MS) was measured with a Bartington MS3 operating with a MS2E
198 sensor. MS measurements (in SI units) were obtained directly from the core surface every 0.5 cm
199 (Fig. 3).

200 Elemental geochemical composition was measured in an X-Ray fluorescence (XRF) Avaatech
201 core scanner® at the University of Barcelona (Spain). A total of thirty-three chemical elements
202 were measured in the XRF core scanner at 10 mm of spatial resolution, using 10 s count time, 10
203 kV X-ray voltage and a X-ray current of 650 µA for lighter elements and 35 s count time, 30 kV
204 X-ray voltage, X-ray current of 1700 µA for heavier elements. Thirty-three chemical elements
205 were measured but only the most representative with a major number of counts were considered
206 (Si, K, Ca, Ti, Fe, Zr, Br and Sr). Results for each element are expressed as intensities in counts
207 per second (cps) and normalized (norm.) for the total sum in cps in every measure (Fig. 3).

208 Total organic carbon (TOC) was analyzed every 2 or 3 cm throughout the core. Samples were
209 previously decalcified with 1:1 HCl in order to eliminate the carbonate fraction. The percentage
210 of organic Carbon (OC %) was measured in an Elemental Analyzer Thermo Scientific Flash
211 2000 model from the Scientific Instrumentation Centre of the University of Granada (Spain).
212 Percentage of TOC per gram of sediment was calculated from the percentage of organic carbon
213 (OC %) yielded by the elemental analyzer, and recalculated by the weight of the sample prior to
214 decalcification (Fig. 3).

215 **3.3 Pollen and NPP**

216 Samples for pollen analysis (1-3 cm³) were taken every 1 cm throughout the core. Pollen
217 extraction methods followed a modified Faegri and Iversen (1989) methodology. Processing
218 included the addition of *Lycopodium* spores for calculation of pollen concentration. Sediment
219 was treated with NaOH, HCl, HF and the residue was sieved at 250 mm previous to an acetolysis
220 solution. Counting was performed using a transmitted light microscope at 400 magnifications to
221 an average pollen count of ca. 260 terrestrial pollen grains. Fossil pollen was identified using
222 published keys (Beug, 1961) and modern reference collections at University of Granada (Spain).
223 Pollen counts were transformed to pollen percentages based on the terrestrial pollen sum,
224 excluding aquatics. The palynological zonation was executed by cluster analysis using twelve
225 different pollen taxa- *Olea*, *Pinus* undifferentiated, deciduous *Quercus*, evergreen *Quercus*,
226 *Pistacia*, Ericaceae, *Artemisia*, Asteroideae, Cichorioideae, Amaranthaceae and Poaceae
227 (Grimm, 1987) (Fig. 4). Non-pollen palynomorphs (NPP) include fungal and algal spores, and
228 thecamoebians (testate amoebae). The NPP percentages were calculated and represented with
229 respect to the terrestrial pollen sum (Fig. 4). Furthermore, some pollen taxa were grouped,
230 according to present-day ecological bases, in Mediterranean forest and xerophytes (Fig. 4). The
231 Mediterranean forest taxa is composed of *Quercus* total, *Olea*, *Phillyrea* and *Pistacia*. The
232 xerophyte group includes *Artemisia*, *Ephedra*, and Amaranthaceae.

233 4 Results

234 4.1 Chronology and sedimentation rates

235 The age-model of the studied Padul-15-05 core (Fig. 2) shows that the top 115 cm continuously
236 cover approximately the last ca. 4700 cal yr BP, being the age constrained by fourteen AMS ¹⁴C
237 dates (Table 1). Five distinct sediment accumulation rate (SAR) intervals can be differentiated
238 between 0 and 122.96 cm based on the linear interpolation between radiocarbon dates in the
239 studied core (Fig. 2).

240 4.2 Lithology, MS, XRF and TOC

241 The lithology of the upper ca. 115 cm of the Padul-15-05 sediment core was mainly deduced
242 from a visual inspection together with the element geochemical composition (XRF) and the
243 correlation of these data, and the MS of the split cores. In addition, this information was
244 complemented with the TOC (Fig. 3).

245 A Linear r (Pearson) correlation was calculated for the XRF data, the correlation for the
246 inorganic geochemical elements show us two different groups of elements that covary (Table 2):
247 Group 1) Si, K, Ti, Fe and Zr with a high positive correlation between them; Group 2) Ca, Br
248 and Sr have negative correlation with Group 1. The lithology for this sedimentary sequence
249 consists in clays with variable carbonates, siliciclastics and organic content (Fig. 3). Based on
250 this, the sequence is subdivided in two principal sedimentary units. The bottom of the record
251 corresponds with Unit 1, characterized principally by lower values of MS and higher values of
252 Ca. The top of the sequence can be subdivided in Unit 2, in which the mineralogical composition
253 is lower in Ca with higher values of MS in correlation with mostly siliciclastics elements (Si, K,
254 Ti, Fe and Zr). Within these two units, four different facies can be identified by visual inspection
255 and by the elemental geochemical composition and TOC of the sediments. *Facies* 1, between
256 115-110 cm depth (ca. 4700 to 4650 cal yr BP) and 89-80 cm depth (ca. 4300 to 4000 cal yr BP),
257 are characterized by dark brown organic clays that bear charophytes and plant remains. They are

258 also depicted by relative higher values of TOC values (Fig. 3). *Facies* 2, between 110-89 cm
259 depth (ca. 4650 to 4300 cal yr BP) and 80-42 cm depth (ca. 4000 to 1600 cal yr BP), are made up
260 of brown clays, with the occurrence of gastropods and charophytes. These are also characterized
261 with decreasing TOC values. *Facies* 3, between 42-28 cm depth (ca. 1600 to 450 cal yr BP), are
262 characterized by grayish brown clays with the occurrence of gastropods, and lower values of
263 TOC, the increasing trend in MS and in siliciclastic elements. *Facies* 4, between 28-0 cm/ ca.
264 450 cal yr BP to Present, are made up of light grayish brown clays and feature a strong increase
265 in siliciclastic linked to a strong increase in MS.

266 **4.3 Pollen and NPP**

267 A total of seventy-two pollen taxa were identified but only the most representative taxa are here
268 plotted in a summary pollen diagram (Fig. 4). Selected NPP percentages are also displayed in
269 Figure 4. Four pollen zones (Fig. 4) were visually identified with the help of a cluster analysis
270 using the program CONISS (Grimm, 1987). Pollen zones are described below:

271 **4.3.1 Zone Padul-15-05-1 [~4720 to 3400 cal yr BP/ ~2800 to 1450 BCE (115-65 cm)]**

272 Zone 1 is characterized by the abundance of Mediterranean forest species reaching up to ca. 70
273 %. Another important taxon in this zone is *Pinus*, with average values around 18 %. Herbs are
274 largely represented by Poaceae, averaging around 10 %, and reaching up to ca. 25 %. This pollen
275 zone is subdivided into subzones-1a, 1b and 1c (Fig. 4). The principal characteristic that
276 differentiate subzone-1a to subzone-1b (boundary at ca. 4650 cal yr BP/ca. 2700 BCE) is the
277 decrease in Poaceae from an average value of ca. 18 to 10 %, the increase in *Pinus* from ca. 7 to
278 18 %, and the appearance of cf. *Vitis*. The decrease in Mediterranean forest to average values
279 around 40 %, the increase in *Pinus* to average values around 25 % and a progressive increase in
280 Ericaceae with average occurrences from ca. 6 to 11 %, allow to discern subzones 1b and 1c
281 (boundary at ca. 3950 cal yr BP).

282 **4.3.2. Zone Padul-15-05-2 [~3400 to 1550 cal yr BP/~1450 BCE to 400 CE (65-41 cm)]**

283 The main features of this zone are the increase in Ericaceae up to ca. 16 % and in deciduous
284 *Quercus*, reaching values around 20 %. Therefore, the Mediterranean forest component
285 progressively decreased to values around 34 %. Some herbs such as Cichorioideae became more
286 abundant reaching average occurrences around 7 %. This pollen zone can be subdivided in
287 subzones 2a and 2b with a boundary at ~2850 cal yr BP (~900 BCE). The principal
288 characteristics that differentiate these subzones is marked by the increase in Mediterranean forest
289 types and the increasing trend in deciduous *Quercus* and Ericaceae. The increase in
290 *Botryococcus* averages ca. 4 to 9 % and the expansion of *Mougeotia* and *Zygnum* type are also
291 noticeable.

292 **4.3.3 Zone Padul-15-05-3 [~1550 to 450 cal yr BP/~400 CE to 1500 CE (41-29 cm)]**

293 This zone is distinguished by the maximum depletion of Mediterranean forest elements.
294 Cichorioideae reached average values of about 40 %. The decrease in Ericaceae is also
295 significant. A decrease in *Botryococcus* and other algal remains is observed in this zone,
296 although there is an increase in other Thecamoebians from average values <1 % to 10 %. This
297 pollen zone is subdivided in subzones 3a and 3b at ~1000 cal yr BP (~950 CE). The main

298 features that differentiate these subzones are the increase in *Olea* from subzone 3a to 3b from
299 average values of ca. 1 to 5 %. The increasing trend in Poaceae is also a feature in this subzone,
300 as well as the slight increase in Asteroideae at the top. Significant changes are documented in
301 NPP percentages in this subzone with the expansion of some fungal remain such as *Tilletia* and
302 *Glomus* type. Furthermore, a decrease in *Botryococcus* and the near disappearance of other algal
303 remains such as *Mougeotia* occurred.

304 4.3.4 Zone Padul-15-05-4 [~last 450 cal yr BP/~ 1500 CE to Present (29-0 cm)]

305 The main feature in this zone is the significant increase in *Pinus*, reaching maximum values (ca.
306 32 %), an increase in Poaceae (ca. 40 %) and the decrease in Cichorioideae (from average
307 occurrences of ca. 44 to 16 %). Other important changes are the nearly total disappearance of
308 some shrubs such as *Pistacia* and a decreasing trend in Ericaceae, as well as an important
309 decrease in Mediterranean forest pollen. An increase in wetland pollen taxa, mostly *Typha* also
310 occurred. A significant increase in xerophytes, with the expansion of Amaranthaceae to ~14 %,
311 is also observed in this period. Other herbs such as *Plantago*, Polygonaceae and Convolvulaceae
312 show moderate increases. This zone 4 is subdivided into subzones 4a and 4b (Fig. 4). The top of
313 the record, which corresponds approximately 1830 CE to Present, is characterized by the
314 subzone 4b, the main characteristic that differentiate subzone 4b from the previous 4a is a
315 decrease in some herbs such as Cichorioideae. However, an increase in some xerophytic herbs
316 such as Amaranthaceae occurred. The increase in *Plantago* is also significant during this period.
317 A noteworthy increase in *Pinus* (from an average of ca. 14 to 27 %) and a slight increase in *Olea*
318 and evergreen *Quercus* are also characteristic of this subzone. With respect to NPP, there is an
319 increase in thecamoebians such as *Arcella* type and in the largely coprophilous sordariaceous
320 (Sordariales) group. This zone also documents the decrease in fresh-water algal spores, in
321 *Botryococcus* concomitant with *Mougeotia* and *Zygnuma* type.

322 4.4 Estimated lake level reconstruction

323 Different local proxies from the Padul-15-05 record [Si, Ca, TOC, MS, Hygrophytes (made up of
324 Cyperaceae and *Typha*), Poaceae and Algae (including Botryococcus, Zygnuma type
325 and Mougeotia) groups] have been depicted in order to understand the relationship between
326 lithological, geochemical, and palynological variability and the water lake level oscillations.
327 Sediments with higher values of TOC (more algae and hygrophytes), rich in Ca (related with the
328 occurrence of shells and charophytes remains) most likely characterized a shallow water
329 environment. The absence of aquatic shells, decreasing Ca and a lower TOC and/or a higher
330 input of clastic material (higher MS and Si values) into the lake, could be related with lake level
331 lowering, and a shallower wetland environment (increase in Poaceae) (Fig. 5).

332 4.5 Spectral analysis

333 Spectral analysis was performed on selected pollen and NPP time series (Mediterranean forest
334 and *Botryococcus*), as well as TOC in order to identify millennial- and centennial-scale
335 periodicities in the Padul-15-05 record. The mean sampling resolution for pollen and NPP is ca.
336 50 yr and for geochemical data is ca. 80 yr. Statistically significant cycles, above the 90, 95 and
337 99 % of confident levels, were found around 800, 680, 300, 240, 200, 170 (Fig. 7).

338 5 Discussion

339 Different proxies have been used in this study to interpret the paleoenvironmental and
340 hydrodynamic changes recorded in the Padul peat bog sedimentary record during the last 4700
341 cal yr BP. Palynological analysis (pollen and NPP) is commonly used as a proxy for climate
342 change, lake level variations and human impact and land uses (e.g. Faegri and Iversen, 1990; van
343 Geel et al., 1983). In this study, we used the variations between Mediterranean forest taxa,
344 xerophytes and algal communities for paleoclimatic variability and the occurrence of
345 nitrophilous and ruderal plant communities and some NPPs for identifying human influence in
346 the study area (Fig. 4). Variations in arboreal pollen (AP, including Mediterranean tree species)
347 have previously been used in the Sierra Nevada records as a proxy for humidity changes
348 (Jiménez-Moreno and Anderson, 2012; Ramos-Román et al., 2016). The abundance of the
349 Mediterranean forest has been used as a proxy for climate change in other studies in the western
350 Mediterranean region, with higher forest development generally meaning higher humidity
351 (Fletcher et al., 2013; Fletcher and Sánchez-Goñi, 2008). On the other hand, increases in
352 xerophyte pollen taxa (i.e., *Artemisia*, *Ephedra*, Amaranthaceae) have been used as an indication
353 of aridity in this area (Anderson et al., 2011; Carrión et al., 2007).
354 The chlorophyceae alga *Botryococcus* sp. has been described as an indicator of freshwater
355 environments, in relatively productive fens, temporary pools, ponds or lakes (Guy-Ochluss, 1992). The high visual and statistical correlation between *Botryococcus* from Padul-15-05 and
356 North Atlantic temperature estimations (Bond et al., 2001; $r = -0.63$; $p < 0.0001$; between ca.
357 4700 to 1500 cal ka BP – the decreasing and very low *Botryococcus* occurrence in the last 1500
358 cal yr BP makes this correlation moderate: $r=-0.48$; $p < 0.0001$ between 4700 and -65 cal yr BP)
359 seems to show that in this case *Botryococcus* is driven by temperature change and would reflect
360 variations in lake productivity (increasing with warmer water temperatures).
361 In addition to the palynological analysis, variations in the lithology, geochemistry and
362 macrofossil remains (gastropod shells and charophytes) from the Padul-15-05 core helped us
363 reconstruct the estimated lake level and the local environment changes in the Padul peat bog.
364 Several previous studies on Late Holocene lake records from the Iberian Peninsula show that
365 lithological changes can be used as a proxy for lake level reconstruction (Martín-Puertas et al.,
366 2011; Morellón et al., 2009; Riera et al., 2004). For example, carbonate sediments formed by
367 biogenic remains of gastropods and charophytes are indicative of shallow lake waters (Riera et
368 al., 2004). Furthermore, van Geel et al. (1983), described occurrences of *Mougeotia* and
369 *Zygnumataceae* type (Zygnemataceae) as typical of shallow water environments. The increase in
370 organic matter accumulation deduced by TOC (and Br) could be considered as characteristic of
371 high productivity (Kalugin et al., 2007) in these shallow water environments. On the other hand,
372 increases in clastic input in lake sediments have been interpreted as due to lowering of lake level
373 and more influence of terrestrial-fluvial deposition in a very shallow/ephemeral lake (Martín-
374 Puertas et al., 2008). We used the variations between those proxies to estimate water level (Fig.
375 5).
376 Nitrophilous and ruderal pollen taxa (*Convolvulus*, *Plantago lanceolata* type, Urticaceae type
377 and/or *Polygonum aviculare* type) are also very useful as proxies for human impact (Riera et al.,
378 2004). Some species of Cichorioideae have also been described in different studies from the
379 Iberian Peninsula as nitrophilous taxa (Abel-Schaad and López-Sáez, 2013). At the same time,
380 NPP taxa such as some coprophilous fungi, Sordariales and thecamoebians are also used as
381 indicators of anthropization and land use (Carrión et al., 2007; Ejarque et al., 2015; van Geel et
382 al., 1989; Riera et al., 2006). *Tilletia* a grass-parasitizing fungi has been described as an indicator
383

384 of grass cultivation in other Iberian records (Carrión et al., 2001b). In this study we also used the
385 NPP mycorrhizal fungus *Glomus* sp. as a proxy for erosive activity. This interpretation comes
386 from a study from van Geel et al. (1989), who correlated erosive events with elevated
387 percentages of *Glomus cf. fasciculatum*.

388 5.1 Late Holocene aridification trend

389 This study shows that a progressive aridification trend occurred during at least the last ca. 4700
390 cal yr BP in the southern Iberian Peninsula. The increase in aridity is shown in the Padul-15-05
391 core by a progressive decrease in Mediterranean forest component and the increase in herbs
392 (Figs. 4 and 7). Lake level interpretations from our record agree with the pollen and show an
393 overall decrease during the Late Holocene, from a shallow water table containing relatively
394 abundant organic matter (high TOC, indicating higher productivity), gastropods and charophytes
395 (high Ca values) to a low-productive ephemeral/emerged environment (high clastic input and MS
396 and decrease in Ca) (Fig. 5). This progressive aridification confirmed by the increase in
397 siliciclastics pointing to a change towards ephemeral (even emerged) environments became more
398 prominent since the last ca. 1550 cal yr BP and then enhanced again in the last 300 cal yr BP to
399 Present. *Glomus*, a spore from mycorrhizal fungi that occur in soils (van Geel et al., 1989),
400 follows a similar pattern of change, which probably points to enhanced soil erosion in the
401 catchment area during the last 1550 cal yr BP. Furthermore, the increase in some proxies
402 indicating human land use during this last period suggests that humans were more active in this
403 area since then.

404 These results are supported by previous studies from the Mediterranean area using different
405 proxies documenting an aridification trend since the Middle Holocene (Carrión, 2002; Carrión et
406 al., 2010a; Fletcher et al., 2013; Fletcher and Sánchez-Goñi, 2008; Jiménez-Espejo et al., 2014;
407 Jiménez-Moreno et al., 2015). In the western Mediterranean region this decline in forest
408 development during the Middle and Late Holocene is related with a decrease in summer
409 insolation (Fletcher et al., 2013; Jiménez-Moreno and Anderson, 2012). This would produce a
410 progressive cooling, with a reduction in the length of the growing season as well as a decrease in
411 the sea-surface temperature (Marchal et al., 2002), generating a decrease in the land-sea contrast
412 that would be reflected in a reduction of the wind system and a reduced precipitation gradient
413 from sea to shore during the fall-winter season. Also, a reorganization of the general atmospheric
414 circulation with a northward shift of the westerlies - a long-term enhanced positive NAO trend -
415 has been interpreted, inducing drier conditions in this area since 6000 cal yr BP (Magny et al.,
416 2012). The aridification trend can clearly be seen in the nearby alpine records from the Sierra
417 Nevada, where there was little influence by human activity (Anderson et al., 2011; Jiménez-
418 Moreno et al., 2013; Jiménez-Moreno and Anderson, 2012; Ramos-Román et al., 2016).

419 5.2 Millennial- and centennial-scale climate variability in the Padul peat bog during the 420 Late Holocene

421 The multi-proxy paleoclimate record from Padul-15-05 shows an overall aridification trend.
422 However, this trend seems to be modulated by millennial- and centennial-scale climatic
423 variability.

424 5.2.1 Aridity pulses around 4200 (4500, 4300 and 4000 cal yr BP) and around 3000 cal yr 425 BP (3300 and 2800 cal yr BP)

426 Marked aridity pulses are registered in the Padul-15-05 record around 4200 and 3000 cal yr BP
427 (Unit 1; Pollen zones 1 an 2a; Figs. 6 and 7). These arid pulses are mostly evidenced in this
428 record by declines in Mediterranean forest taxa, as well as lake level drops and/or cooling
429 evidenced by a decrease in organic component as TOC and the decrease in *Botryococcus* algae.
430 However, a discrepancy between the local and regional occurs between 3000-2800 cal yr BP,
431 with an increase in the estimated lake level and a decrease in the Mediterranean forest during the
432 late Bronze Age until the early Iron Age (Figs. 6 and 7). The disagreement could be due to
433 deforestation by humans during a very active period of mining in the area observed as a peak in
434 lead pollution in the alpine records from Sierra Nevada (García-Alix et al., 2013). The aridity
435 pulses agree regionally with recent studies carried out at higher in elevation in the Sierra Nevada,
436 a decrease in AP percentage in Borreguil de la Caldera record around 4000-3500 cal yr BP
437 (Ramos-Román et al., 2016), high percentage of non-arboreal pollen around 3400 cal ka BP in
438 Zoñar lake [Southern Córdoba Natural Reserve; (Martín-Puertas et al., 2008)], and lake
439 desiccation at ca. 4100 and 2900 cal yr BP in Lake Siles (Carrión et al., 2007). Jalut et al. (2009)
440 compared paleoclimatic records from different lakes in the western Mediterranean region and
441 also suggested a dry phase between 4300 to 3400 cal yr BP, synchronous with this aridification
442 phase. Furthermore, in the eastern Mediterranean basin other pollen studies show a decrease in
443 arboreal pollen concentration toward more open landscapes around 3.7 ka cal BP (Magri, 1999).
444 Significant climatic changes also occurred in the Northern Hemisphere at those times and polar
445 cooling and tropical aridity are observed at ca. 4200-3800 and 3500-2500 cal yr BP; (Mayewski
446 et al., 2004), cold events in the North Atlantic [cold event 3 and 2; (Bond et al., 2001)], decrease
447 in solar irradiance (Steinhilber et al., 2009) and humidity decreases in the eastern Mediterranean
448 area at 4200 cal yr BP (Bar-Matthews et al., 2003) that could be related with global scale climate
449 variability (Fig. 6). These generally dry phases between 4.5 and 2.8 in Padul-15-05 are generally
450 in agreement with persistent positive NAO conditions during this time (Olsen et al., 2012).
451 The high-resolution Padul-15-05 record shows that climatic crises such as the one occurred at ca.
452 4200 cal yr BP, which seems to be recorded worldwide (Booth et al., 2005), are the product of
453 the sum of more than one single climatic event (i.e., ca. 4500, 4300, 4000 cal yr BP) and thus are
454 affected by climatic variability at centennial-scales.

455 5.2.2 Iberian-Roman Humid Period (~2600 to 1600 cal yr BP)

456 High relative humidity is recorded in the Padul-15-05 record between ca. 2600 and 1600 cal yr
457 BP, synchronous with the well-known Iberian-Roman Humid Period (IRHP; between 2600 and
458 1600 cal yr BP; (Martín-Puertas et al., 2009). This is interpreted in our record due to an increase
459 in the Mediterranean forest species at that time (Unit 1; Pollen Zone 2.b; Figs. 6 and 7). In
460 addition, there is a simultaneous increase in *Botryococcus* algae, which is probably related to
461 higher productivity during warmer conditions. Evidence of a wetter climate around this period
462 has also been shown in other regional records and several alpine records from Sierra Nevada. For
463 example, Jiménez-Moreno et al. (2013) studying a sediment record from the Laguna de la Mula,
464 showed an increase in deciduous *Quercus* in correlation with the maximum in algae between
465 2500 to 1850 cal yr BP, also evidencing the most humid period of the Late Holocene. A
466 geochemical study from the Laguna de Río Seco (also in Sierra Nevada) also evidenced humid
467 conditions around 2200 cal yr BP by the decrease in Saharan dust input and the increase in
468 detritic sedimentation into the lake suggesting higher rainfall (Jiménez-Espejo et al., 2014). In
469 addition, Ramos-Román et al. (2016) showed an increase in AP in the Borreguil de la Caldera
470 record around 2200 cal yr BP, suggesting an increase in humidity at that time.

471 Other records from the Iberian Peninsula also show this pattern to wetter conditions during the
 472 IRHP. For example, high lake levels are recorded in Zoñar Lake in southern Spain between 2460
 473 to 1600 cal yr BP, only interrupted by a relatively arid pulse between 2140 and 1800 cal yr BP
 474 (Martín-Puertas et al., 2009). An increase in rainfall is described in the central region of the
 475 Iberian Peninsula in a study from the Tablas de Daimiel National Park between 2100 and 1680
 476 cal yr BP (Gil García et al., 2007). Deeper lake levels at around 2650 to 1580 cal yr BP, also
 477 interrupted by an short arid event at ca. 2125-1790 cal yr BP, were observed to the north, in the
 478 Iberian Range (Currás et al., 2012). The fact that the Padul-15-05 record also shows a relatively
 479 arid-cold event between 2150-2050 cal yr BP, just in the middle of this relative humid-warm
 480 period, seems to point to a common feature of centennial-scale climatic variability in many
 481 western Mediterranean and North Atlantic records (Fig. 6). Humid climate conditions at around
 482 2500 cal yr BP are also interpreted in previous studies from lake level reconstructions from
 483 Central Europe (Magny, 2004). Increases in temperate deciduous forest are also observed in
 484 marine records from the Alboran Sea around 2600 to 2300 cal yr BP, also pointing to high
 485 relative humidity (Combourieu Nebout et al., 2009; Fletcher et al., 2007). Overall humid
 486 conditions between 2600 and 1600 cal yr BP seem to agree with predominant negative NAO
 487 reconstructions at that time, which would translate into greater winter (and thus more effective)
 488 precipitation in the area triggering more development of forest species in the area.
 489 Generally warm conditions are interpreted between 1900 and 1700 cal yr BP in the
 490 Mediterranean Sea, with high sea surface temperatures (SSTs), and in the North Atlantic area,
 491 with the decrease in Drift Ice Index. In addition, persistent positive solar irradiance occurred at
 492 that time. The increase in *Botryococcus* algae reaching maxima during the IRHP also seems to
 493 point to very productive and perhaps warmer conditions in the Padul peat bog area (Fig. 6).

494 5.2.3 DA and MCA – aridity between ~1550 cal yr BP and 600 cal yr BP

495 Enhanced aridity occurred right after the IRHP in the Padul peat bog area between ca. 1550 and
 496 600 cal yr BP (ca. 400 - 1350 CE). This is deduced in the Padul-15-05 record by a significant
 497 forest decline, with a prominent decrease in Mediterranean forest, an increase in Cichorioideae
 498 herbs and the decline in the estimated water level (Unit 1; Pollen Zone 3; Figs. 4 and 7). A
 499 significant change since the end of the IRHP took place in the lake environment, suggesting the
 500 transition from a shallow water table to an ephemeral environment. This is deduced by the
 501 disappearance of charophytes, a significant decrease in Algae component and higher Si and MS
 502 and lower TOC values (Unit 1; Figs. 6 and 7).
 503 This arid phase could be separated into two different periods. The first period occurred between
 504 ca. 1550 cal yr BP (ca. 400 CE) and ca. 1100 cal yr BP (ca. 900 CE) and is characterized by a
 505 decreasing trend in Mediterranean forest and *Botryococcus* taxa and the increase in
 506 Cichorioideae. This period corresponds with the Dark Ages [from ca. 500 to 900 CE; (Moreno et
 507 al., 2012)]. A visual correlation between the decrease in Mediterranean forest, the increase in the
 508 Drift Ice Index in the North Atlantic record (cold event 1; Bond et al., 2001), the decrease in
 509 SSTs in the Mediterranean Sea and maxima in positive NAO reconstructions suggests drier and
 510 colder conditions during this time (Fig. 6). Other Mediterranean and central-European records
 511 agree with our climate interpretations, for example, a decrease in forest extent is shown in a
 512 marine record from the Alboran Sea (Fletcher et al., 2013) and a decrease in lake levels is also
 513 observed in Central Europe (Magny et al., 2004) pointing to aridity during the DA. Evidences of
 514 aridity during the DA have been shown too in the Mediterranean part of the Iberian Peninsula, for
 515 instance, cold and arid conditions were suggested in the northern Betic Range by the increase in

xerophytic herbs around 1450 and 750 cal yr BP (Carrión et al., 2001a) and in southeastern Spain by a forest decline in lacustrine deposits around 1620 and 1160 cal yr BP (Carrión et al., 2003). Arid and colder conditions during the Dark Ages (around 1680 to 1000 cal yr BP) are also suggested for the central part of the Iberian Peninsula using a multiproxy study of a sediment record from the Tablas de Daimiel Lake (Gil García et al., 2007). A second period that we could differentiate within this overall arid phase occurred around 1100 to 600 cal yr BP/900 to 1350 CE, during the well-known MCA (900 to 1300 CE after Moreno et al., 2012). During this period the Padul-15-05 record shows a slight increasing trend in the Mediterranean forest taxa with respect to the DA, but the decrease in *Botryococcus* and the higher abundance of herbs still point to overall arid conditions. This change could be related to an increase in temperature, favoring the development of temperate forest species, and would agree with inferred increasing temperatures in the North Atlantic areas, as well as the increase in solar irradiance and the increase in SSTs in the Mediterranean Sea (Fig. 7). This hypothesis would agree with the reconstruction of persistent positive NAO and overall warm conditions during the MCA in the western Mediterranean (see synthesis in Moreno et al., 2012). A similar pattern of increasing xerophytic vegetation during the MCA is observed in alpine peat bogs and lakes in the Sierra Nevada (Anderson et al., 2011; Jiménez-Moreno et al., 2013; Ramos-Román et al., 2016) and arid conditions are shown to occur during the MCA in southern and eastern Iberian Peninsula deduced by increases in salinity and lower lake levels (Corella et al., 2013; Martín-Puertas et al., 2011). However, humid conditions have been reconstructed for the northwestern of the Iberian Peninsula at this time (Lebreiro et al., 2006; Moreno et al., 2012), as well as northern Europe (Martín-Puertas et al., 2008). The different pattern of precipitation between the northwestern Iberian Peninsula / northern Europe and the Mediterranean area is undoubtedly a function of the well-known NAO dipole in precipitation pattern (Trouet et al., 2009).

5.2.4 The last ~600 cal yr BP: LIA (1350-1850 CE) and IE (1850 CE-Present)

Two climatically different periods can be distinguished during the last ca. 600 cal yr BP (end of Zone 3b to Zone 4; Fig. 4) in the area. However, the climatic signal is more difficult to interpret due to a higher human impact at that time. The first phase around 1350-1450 CE was characterized by increasing relative humidity by the decrease in xerophytes and the increase in Mediterranean forest taxa and *Botryococcus* after a period of decrease during the DA and MCA, corresponding to the LIA. The second phase is characterized here by the decrease in the Mediterranean forest around 1700-1850 CE, pointing to a return to more arid conditions during the last part of the LIA (Figs. 4 and 7). This climatic pattern agrees with an increase in precipitation by the transition from positive to negative NAO mode and from warmer to cooler conditions in the North Atlantic area during the first phase of the LIA and a second phase characterized by cooler (cold event 0; Bond et al., 2001) and drier conditions (Fig. 6). A stronger variability in the SSTs is described in the Mediterranean Sea during the LIA (Fig. 6). Mayewski et al. (2004) described a period of climate variability during the Holocene at this time (600 to 150 cal yr BP) suggesting a polar cooling but more humid in some parts of the tropics. Regionally, (Morellón et al., 2011) also described a phase of more humid conditions between 1530 to 1750 CE in a lake sediment record from NE Spain. An alternation between wetter to drier periods during the LIA are also shown in the nearby alpine record from Borreguil de la Caldera in the Sierra Nevada mountain range (Ramos-Román et al., 2016).

560 The environmental transition from ephemeral to emerged conditions, observed in the last ca.
561 1550 cal yr BP (Unit 1; Fig. 5), intensified in the last ca. 300 cal yr BP. This is shown by the
562 highest MS and Si values the increase in wetland plants and the stronger decrease in Ca and
563 organic components (TOC) in the sediments in the uppermost part of the Padul-15-05 record
564 (Unit 2; Figs. 3 and 6).

565 5.3 Centennial-scale variability

566 Time series analysis has become important in determining the recurrent periodicity of cyclical
567 oscillations in paleoenvironmental sequences (e.g. Jiménez-Espejo et al., 2014; Ramos-Román et
568 al., 2016; Rodrigo-Gámiz et al., 2014; Fletcher et al., 2013). This analysis also assists in
569 understanding possible relationships between the paleoenvironmental proxy data and the
570 potential triggers of the observed cyclical changes: i.e., solar activity, atmospheric, oceanic
571 dynamics and climate evolution during the Holocene. The cyclostratigraphic analysis on the
572 pollen (Mediterranean forest; regional signal), algae (*Botryococcus*; local signal) and TOC (local
573 signal) times series from the Padul-15-05 record evidence centennial-scale cyclical patterns with
574 periodicities around 800, 680, 300, 240, 200 and 170 years above the 90 % confidence levels
575 (Fig. 7).

576 Previous cyclostratigraphic analysis in Holocene western Mediterranean records suggest cyclical
577 climatic oscillations with periodicities around 1500 and 1750 yr (Fletcher et al., 2013; Jiménez-
578 Espejo et al., 2014; Rodrigo-Gámiz et al., 2014). Other North Atlantic and Mediterranean
579 records also present cyclicity in their paleoclimatic proxies of ca. 1600 yr (Bond et al., 2001;
580 Debret et al., 2007; Rodrigo-Gámiz et al., 2014). However, this cycle is absent from the
581 cyclostratigraphic analysis in the Padul-15-05 record (Fig. 7). In contrast, the spectral analysis
582 performed in the Mediterranean forest time series from Padul peat bog record, pointing to
583 cyclical hydrological changes, shows a significant ~800 yr cycle that could be related to solar
584 variability (Damon and Sonett, 1991) or could be the second harmonic of the ca. ~1600 yr
585 oceanic-related cycle (Debret et al., 2009). A very similar periodicity of ca. 760 yr is detected in
586 the *Pinus* forest taxa, also pointing to humidity variability, from the alpine Sierra Nevada site of
587 Borreguil de la Caldera and seems to show that this is a common feature of cyclical
588 paleoclimatic oscillation in the area.

589 A significant ~680 cycle is shown in the *Botryococcus* time series most likely suggesting
590 recurrent centennial-scale changes in temperature (productivity) and water availability. A similar
591 cycle is shown in the *Artemisia* signal in an alpine record from Sierra Nevada (Ramos-Román et
592 al., 2016). This cycle around ~650 yr is also observed in a marine record from the Alboran Sea,
593 and was interpreted as the secondary harmonic of the 1300 yr cycle that those authors related
594 with cyclic thermohaline circulation and sea surface temperature changes (Rodrigo-Gámiz et al.,
595 2014).

596 A statistically significant ~300 yr cycle is shown in the Mediterranean forest taxa and TOC from
597 the Padul-15-05 record suggesting shorter-scale variability in water availability. This cycle is
598 also observed in the cyclical *Pinus* pollen data from Borreguil de la Caldera at higher elevations
599 in the Sierra Nevada (Ramos-Román et al., 2016). This cycle could be principally related to
600 NAO variability as observed by Olsen et al. (2012), which follows variations in humidity
601 observed in the Padul-15-05 record. NAO variability also regulates modern precipitation in the
602 area.

603 The *Botryococcus* and TOC time series shows variability with a periodicity around ~240, 200
604 and 164 yrs. Sonnet et al. (1984) described a significant cycle in solar activity around ~208 yr

605 (Suess solar cycle), which could have triggered our ~200 cyclicity. The observed ~240 yr
606 periodicity in the Padul-15-05 record could be either related to variations in solar activity or due
607 to the mixed effect of the solar together with the ~300 yr NAO-interpreted cycle and could point
608 to a solar origin of the centennial-scale NAO variations as suggested by previously published
609 research (Lukianova and Alekseev, 2004; Zanchettin et al., 2008). Finally, a significant ~170 yr
610 cycle has been observed in both the Mediterranean forest taxa and *Botryococcus* times series
611 from the Padul-15-05 record. A similar cycle (between 168–174 yr) was also described in the
612 alpine pollen record from Borreguil de la Caldera in Sierra Nevada (Ramos-Román et al., 2016),
613 which shows that it is a significant cyclical pattern in climate, probably precipitation, in the area.
614 This cycle could be related to the previously described ~170 yr cycle in the NAO index (Olsen et
615 al., 2012), which would agree with the hypothesis of the NAO controlling millennial- and
616 centennial-scale environmental variability during the Late Holocene in the area (García-Alix et
617 al., 2017; Ramos-Román et al., 2016).

618 5.4 Human activity

619 Humans probably had an impact in the area since Prehistoric times, however, the Padul-15-05
620 multiproxy record shows a more significant human impact during the last ca. 1550 cal yr BP,
621 which intensified in the last ca. 500 cal yr BP (since 1450 CE to Present). This is deduced by a
622 significant increase in nitrophilous plant taxa such as *Cichorioideae*, *Convolvulaceae*,
623 *Polygonaceae* and *Plantago* and the increase in some NPP such as *Tilletia*, coprophilous fungi
624 and thecamoebians (Unit 2; Pollen Zone 4; Fig. 4). Most of these pollen taxa and NPPs are
625 described in other southern Iberian paleoenvironmental records as indicators of land uses, for
626 instance, *Tilletia* and covarying *Cichorioideae* and *Convolvulaceae* have been described as
627 indicators of farming (e.g. Carrión et al., 2001b). Interestingly, these taxa being to decline around
628 ~1450 CE, coinciding with the higher increase in detritic material into the basin. Climatically,
629 this event coincides with the start of persistent negative NAO conditions in the area (Trouet et
630 al., 2009), which could have further triggered more rainfall and more detritic input into the basin.
631 Bellin et al., 2011 in a study from the Betic Cordillera (southern Iberian Peninsula) demonstrate
632 that soil erosion increase in years with higher rainfall and this could be intensified by human
633 impact. Nevertheless, in a study in the southeastern part of the Iberian Peninsula (Bellin et al.,
634 2013) suggested that major soil erosion could have occurred by the abandonment of agricultural
635 activities in the mountain areas as well as the abandonment of irrigated terrace systems during
636 the Christian Reconquest. Enhanced soil erosion at this time is also supported by the increase in
637 *Glomus* type (Fig. 4).

638 An important change in the sedimentation in the environment is observed during the last ca. 300
639 cal yr BP marked by the stronger increase in MS and Si values. This was probably related with
640 the Padul peat bog water drainage by humans using canals in the late XVIII century for
641 cultivation purposes (Villegas Molina, 1967). The increase in wetland vegetation and higher
642 values of Poaceae could be due to cultivation of cereals or by an increase in the population of
643 *Phragmites australis* (also a Poaceae), very abundant in the Padul peat bog margins at present
644 due to the increase in drained land surface.

645 The uppermost part (last ca. 100 cal yr BP) of the pollen record from Padul-15-05 shows an
646 increasing trend in some arboreal taxa at that time, including Mediterranean forest, *Olea* and
647 *Pinus* (Fig. 4). This change is most likely of human origin and generated by the increase in *Olea*
648 cultivation in the last two centuries, also observed in many records from higher elevation sites
649 from Sierra Nevada, and *Pinus* and other Mediterranean species reforestation in the 20th century

650 (Anderson et al., 2011; Jiménez-Moreno and Anderson, 2012; Jiménez-Moreno et al., 2013;
651 Ramos-Román et al., 2016).

652 **6 Conclusions**

653 Our multiproxy (i.e. lithology, geochemistry, paleontology) analysis from the Padul-15-05
654 sequence has provided a detailed climate reconstruction for the last 4700 ca yr BP for the Padul
655 peat bog area and the western Mediterranean. This study, supported by the comparison with
656 other Mediterranean and North Atlantic records suggests a link between vegetation, atmospheric
657 dynamics and insolation and solar activity during the Late Holocene in this area. A climatic
658 aridification trend occurred during the Late Holocene in the Sierra Nevada and the western
659 Mediterranean area, probably linked with the orbital-scale decreasing trend in summer
660 insolation. This long-term trend is modulated by centennial-scale climate variability as shown by
661 the pollen (Mediterranean forest taxa) algae (*Botryococcus*) and sedimentary and geochemical
662 data in the Padul record. These events are in correlation with regional and global scale climate
663 variability and cold and arid pulses around the 4200 and 3000 cal yr BP that are identified in this
664 study seem to be synchronous with cold events recorded in the North Atlantic and decreases in
665 precipitation in the Mediterranean area, probably linked to persistent positive NAO mode.
666 Moreover, one of the most important humid and warmer periods during the Late Holocene in the
667 Padul area coincides in time with the well-known IRHP, warm and humid conditions in the
668 Mediterranean and North Atlantic regions and overall negative NAO conditions. A drastic
669 decrease in Mediterranean forest taxa towards an open landscape, pointing to colder and
670 enhanced aridity, occurred in two steps (DA and end of the LIA) during the last ca. 1550 cal yr
671 BP. However, this trend was slightly superimposed by a more arid but warmer event coinciding
672 with the MCA and a cold but wetter event during the first part of the LIA. Besides natural
673 climatic and environmental variability, there seems to be intense human activities in the area
674 during the last the last ca. 1550 cal yr BP. This suggests that the natural aridification trend during
675 the Late Holocene in the western Mediterranean region could have been intensified due to the
676 higher human activity in this area.

677 Furthermore, time series analyses done in the Padul-15-05 record show centennial-scale changes
678 in the environment and climate that are coincident with the periodicities observed in solar,
679 oceanic and NAO reconstructions and could show a close cause-and-effect linkage between
680 them.

 1067 (a.8) Algae (%)(a.9) Total organic carbon (TOC %)] (b) Mediterranean forest taxa, with a
 1068 smoothing of three-point in bold. Pink and blue shading indicates Holocene arid and humid
 1069 regionally events, respectively. See the body of the text for the explanation of the lake level
 1070 reconstruction. Mediterranean forest smoothing was made using Analyseries software (Paillard
 1071 et al., 1996). CA = Copper Age; BA = Bronze Age; IA = Iron Age; IRHP = Iberian Roman
 1072 Humid Period; DA = Dark Ages; MCA = Medieval Climate Anomaly; LIA = Little Ice Age; IE
 1073 = Industrial Era.

1075 **Figure 6.** Comparison of the last ca. 4700 yr between different pollen taxa from the Padul-15-05
1076 record, summer insolation for the Sierra Nevada latitude, eastern Mediterranean humidity and
1077 North Atlantic temperature. (a) *Botryococcus* from the Padul-15-05 record, with a smoothing of
1078 three-point in bold (this study). (b) Drift Ice Index (reversed) from the North Atlantic (Bond et
1079 al., 2001). (c) Summer insolation calculated for 37° N (Laskar et al., 2004). (d) Mediterranean
1080 forest taxa from the Padul-15-05 record, with a smoothing of three-point in bold (this study). (e)
1081 Alkenone-SSTs from the Gulf of Lion (Sicre et al., 2016), with a smoothing of four-point in
1082 bold. (f) North Atlantic Oscillation (NAO) index from a climate proxy reconstruction from
1083 Morocco and Scotland (Trouet et al., 2009). (g) North Atlantic Oscillation (NAO) index
1084 (reversed) from a climate proxy reconstruction from Greenland (Olsen et al., 2012). (h) Total
1085 solar irradiance reconstruction from cosmogenic radionuclide from a Greenland ice core
1086 (Steinhilber et al., 2009), with a smoothing of twenty-one-point in bold. Yellow and blue shading
1087 correspond with arid (and cold) and humid (and warm) periods, respectively. Grey dash lines
1088 show a tentative correlation between arid and cold conditions and the decrease in the
1089 Mediterranean forest and *Botryococcus*. Mediterranean forest, *Botryococcus* and solar irradiance
1090 smoothing was made using Analyseries software (Paillard et al., 1996), Alkenone-SSTs
1091 smoothing was made using Past software (http://palaeo-electronica.org/2001_1/past/issue1_01.htm). A linear r (Pearson) correlation was calculated
1092 between *Botryococcus* (detrended) and Drift Ice Index (Bond et al., 2001; $r = -0.63$; $p < 0.0001$;
1093 between ca. 4700 to 1500 cal ka BP – $r = -0.48$; $p < 0.0001$ between 4700 and -65 cal yr BP).
1094 Previously, the data were detrended (only in *Botryococcus*), resampled at 70-yr (linear
1095 interpolation) in order to obtain equally spaced time series and smoothed to three-point average.
1096 CA = Copper Age; BA = Bronze Age; IA = Iron Age; IRHP = Iberian Roman Humid Period;
1097 DA = Dark Ages; MCA = Medieval Climate Anomaly; LIA = Little Ice Age; IE = Industrial Era.
