13

14 **Abstract.** Limited research has focussed on historical droughts during the pre-instrumental weather-recording  
15 period in semi-arid to arid human-inhabited environments. Here we describe the unique nature of droughts over  
16 semi-arid central Namibia (southern Africa) between 1850 and 1920. More particularly, our intention is to  
17 establish temporal shifts of influence and impact that historical droughts had on society and the environment  
18 during this period. This is achieved through scrutinizing documentary records sourced from a variety of archives  
19 and libraries. The primary source of information comes from missionary diaries, letters and reports. These  
20 missionaries were based at a variety of stations across the central Namibian region and thus collectively provide  
21 insight to sub-regional (or site specific) differences in hydro-meteorological conditions, and drought impacts  
22 and responses. Earliest instrumental rainfall records (1891-1913) from several missionary stations or  
23 settlements are used to quantify hydro-meteorological conditions and compare with documentary sources. The  
24 work demonstrates strong-sub-regional contrasts in drought conditions during some given drought events and  
25 the dire implications of failed rain seasons, the consequences of which lasted many months to several years.  
26 The paper advocates that human experience and associated reporting of drought events depends strongly on  
27 social, environmental, spatial and societal developmental situations and perspectives. To this end, the reported  
28 experiences, impacts and responses to drought over this 70 year period portray both common and changeable  
29 attributes through time.

30

31

32

## 33 1. Introduction

34

35 Defining *drought* as a ‘concept’ or as an ‘event’ has received much discussion and debate, which seems ongoing  
36 (e.g. Agnew and Chappell, 1999; Mishra and Singh, 2010; Lloyd-Hughes 2014; Parry et al., 2016). In this  
37 special issue, Brázdil et al. (2019) explore various types and characteristics of drought that are relevant to both  
38 contemporary and historical contexts. These authors use the definition by Wilhite and Pulwarty (2018) to define  
39 drought as ‘a prolonged period of negative deviation in water balance compared to the climatological norm in  
40 a given area’ (p1915). Today most water-requiring situations for agriculture, industry and human consumption  
41 etc, is to a large extent controlled through engineered water transfer schemes, water storage and water  
42 extraction. Hence, contemporary meteorological droughts may not necessarily culminate in agricultural or  
43 economic droughts owing to human-engineered interventions. Conversely, societal expansion with associated  
44 increasing extraction demands on river, lake and sub-surface water resources may induce ecological droughts  
45 that would otherwise not have occurred under given hydro-meteorological conditions. The nature of recent and  
46 contemporary droughts in its various contexts is thus becoming increasingly complex. For this reason, there are  
47 many lessons to learn from the context of historical droughts before the era of enhanced human engineering.

48

49 Although drought is recognized as an environmental and climatic disaster (Mishra and Singh, 2010) which  
50 impacts many sectors such as agriculture, economy, human social dynamics, human health and ecosystems  
51 (Esfahanian et al., 2016), its influence may be highly variable depending on its intensity and duration within  
52 particular climatic regimes. ‘Drought’ is differentiated from ‘aridity’ where the former is considered a  
53 temporary phenomena and the latter a permanent one (Hisdal and Tallaksen, 2000). To this end, it may be a  
54 challenge on perspective to differentiate between drought and aridity in semi-arid regions with a strong bimodal  
55 rainfall distribution. Drought in such already water-stressed regions during ‘normal climatic conditions’, may  
56 have far reaching effects and implications that are not applicable to those of better watered regions such as for  
57 instance central Europe or most parts of North America. Central Namibia is a semi-arid to arid region  
58 characterized by climatic extremes, seasonal aridity and prolonged droughts (Grab and Zumthurm, 2018), and  
59 thus offers an ideal spatial context to explore attributes of historical droughts in an already dry environment.

60

61 Most documentary-based southern African climate chronologies are focussed only on the 19<sup>th</sup> century and end  
62 in 1899 or 1900 (e.g. Nash and Endfield, 2002, 2008; Kelso and Vogel 2007, Grab and Nash, 2010; Nash and  
63 Grab, 2010; Nash et al., 2016, 2018), as was also the case with that for central Namibia (Grab and Zumthurm  
64 2018). However, given that the colonial period with relatively poor instrumental weather records extended into

65 the 20<sup>th</sup> century in many parts of southern Africa, it is perhaps unfortunate that most studies have not extended  
66 their chronologies into the 20<sup>th</sup> century. This is particularly so given that the early 20<sup>th</sup> century experienced  
67 some severe droughts. While Grab and Zumthurm (2018) considered climatological causes for 19<sup>th</sup> century  
68 wet-dry periods over central Namibia, the current paper focuses on the broader context of historical droughts  
69 (consequences, perceptions, socio-economic, socio-political, ecological) during the period 1850-1920.  
70 Extending previous work to 1920 permits the placement of 19<sup>th</sup> century droughts in context with those during  
71 the early 20<sup>th</sup> century in central Namibia. Such a temporal extension is particularly valuable given rapid societal  
72 change associated with technological and infrastructural advancements during the late 19<sup>th</sup>/early 20<sup>th</sup> centuries.  
73 Here we investigate how drought events are portrayed through the lens of early European colonists (primarily  
74 missionaries) in what is today central Namibia. More particularly, we aim to establish the temporal shifts of  
75 influence and impact that historical droughts had on society and the environment during this period, as  
76 portrayed in written documents. At this juncture, it is important to emphasise that the perspectives,  
77 interpretations and views presented are entirely those expressed by European colonists, and in particular from  
78 the spatial context of missionary stations. Regrettably, there are few, if any, 19<sup>th</sup> century documents written  
79 from the perspectives of indigenous communities, who may have had different views on ‘drought’ in central  
80 Namibia. Nonetheless, documentary sources permit, to some extent, to sketch out some of the consequences  
81 and responses to drought by the indigenous population living within relative proximity to mission stations.

82

## 83 **2. Data and Methods**

84

85 This paper is based on early documentary records from central Namibia, but also includes the earliest  
86 instrumental rainfall records from various stations between 1891 and 1913.

87

88 Documentary sources used are the same as those described in detail by Grab and Zumthurm (2018), and  
89 particularly those associated with the Rheinische Missionsgesellschaft [Mission Society](RMS). The Society  
90 released annual reports describing conditions at each (or most) of its mission stations and thus permits  
91 comparison across various sub-regions each year. Details were less comprehensive in earlier years but as more  
92 mission stations were established through the course of time, reporting became increasingly widespread and  
93 better informed (here we refer the reader to Figure 3 in Grab and Zumthurm, 2018). Missionary Carl Hugo  
94 Hahn’s diaries (1850-1859) are an invaluable source of information for the earliest years. The following are  
95 primary sources of documentary records used, especially to understand the context of droughts as experienced  
96 and portrayed through German missionaries: ARRMS (Annual Reports of the Rheinische Missionsgesellschaft-

97 Archives of the Mission 21, Basel, Switzerland), BRM (Berichte der Rheinischen Mission [Reports of the  
98 Rhenish Mission], sourced from the Archives of the Evangelical Lutheran Church, Windhoek, Namibia), and  
99 station chronicles RMG (Rheinische Missionsgesellschaft [Rhenish Mission Society], sourced from the  
100 Archives of the United Evangelical Mission [VEM], Wuppertal, Germany). Prominent missionaries who spent  
101 many years in Namibia include: Carl Hugo Hahn (based at Otjikango), Heinrich Kleinschmidt (based at  
102 Rehoboth), Franz Heinrich Vollmer (based at Rehoboth and later Hoachanas), Johann Carl Böhm (based at  
103 Ameib and Rooibank), Johann Jakob Irle (based at Okahandja and Otjosazu), Friedrich Wilhelm Viehe (various  
104 stations), Johann Heidmann (based at Rehoboth), Philipp Diehl (based at Okahandja and Hoachanas), and Peter  
105 Friedrich Bernsmann (based at Otjimbingue and Omburo). For later years (1894/5 onwards), annual reports,  
106 written by district officials and resident magistrates, are exceptionally valuable written sources of information  
107 as these summarise weather/climatic conditions for various sub-regions each year, as also report on agriculture,  
108 grassland/grazing conditions, disease, health, state of the environment etc. – these were sourced from the  
109 National Archives of Namibia (NAN) in Windhoek. A variety of other relevant documentary sources were  
110 accessed through the Cape Archives Depot (CAD) at the Western Cape Provincial Archives in Cape Town, and  
111 Evangelisch-Lutherische Kirche in Namibia (Evangelical Lutheran Church in Namibia)(ELKIN). Several  
112 detailed travel logs/diaries from individuals (e.g. C.J. Andersson, A. Eriksson, J. Chapman, A. Henker) were  
113 also consulted and recorded at the various archives mentioned above, including also the William Cullen Library  
114 archives at the University of the Witwatersrand.

115

116 We photographed and digitized the earliest available instrumental rainfall records (monthly totals); these were  
117 sourced from the ‘*Mitteilungen aus den Deutschen Schutzgebieten*’, Band XXXII. The records cover the  
118 stations of Rehoboth (south), Windhoek (central highlands) and Okahandja (northern highlands) for the period  
119 1891-1913. Additional station records for the drier western region (Otjimbingue) and wetter eastern region  
120 (Gobabis) are also included, covering the years 1899-1913 and 1897-1913 respectively. These records provide  
121 valuable insight to seasonal and inter-annual rainfall variability during the late 19<sup>th</sup>/early 20<sup>th</sup> centuries, as also  
122 spatial differences in given months, seasons and years (Figure 1). These are then used to compare against the  
123 documentary records and to quantify the severity and duration of drought/dry conditions.

124

125 Grab and Zumthurm (2018) provide methodological detail on how the documentary sources were used to  
126 construct a 19<sup>th</sup> century climate chronology. This chronology was used in our current work, in consultation with  
127 a re-evaluation of the documentary sources, to identify periods of drought between 1850 and 1920. The  
128 instrumental rainfall records assist to not only identify, but also quantify drought events since ca 1891. The

129 documents were further scrutinized to establish characteristics of these droughts (climatic, consequential, social  
130 responsive, environmental), in particular focusing on spatial and temporal contexts (Table 1). A primary  
131 objective is to determine whether droughts may have had changing impacts on society and the environment  
132 through time (i.e. 70 years of the study).

133

134 As is the case with most such studies, it is important to acknowledge potential data and methodological  
135 limitations. In this case, it is important to recognize that the quantity and spatial coverage of information was  
136 variable and more limited in earlier years than latter years, or during years of war/severe conflict. To this end,  
137 some attributes associated with specific droughts may have gone unreported. As already mentioned, the  
138 perspectives presented here are Eurocentric (for reason of data availability) and from particular geographic  
139 settings (i.e. stations located next to rivers or a ‘permanent’ water source) within the broader landscape (space).

140

### 141 **3. Results**

#### 142 **3.1 The historic central Namibian rainfall/drought context**

143

144 Mean annual rainfall across central Namibia (1891-1913) was highly variable, ranging from 384-413mm in the  
145 better watered central and eastern highland regions (Okahandja, Windhoek, Gobabis), to 254mm in the southern  
146 region (Rehoboth) and 174mm in the western part (Otjimbingue) (Figure 1). Inter-annual rainfall variability is  
147 higher (and thus less reliable) in the drier regions (Grab and Zumthurn, 2018). Rainfall is strongly seasonal,  
148 with 95% falling over the austral summer/autumn seasons (November-April). The long dry season (May-  
149 October) rarely has rain of any consequence, and averages from as little as 8mm/pa at Otjimbingue to 25mm/pa  
150 at Gobabis. Several months without any rainfall during the dry season is thus the norm for central Namibia.  
151 This has important implications where the rain season has been considerably below average, as it places  
152 enormous stress, challenges and consequences for surviving the long dry months. Vegetation patterns, animal  
153 movements, and human economies during pre-colonial times were adapted to these semi-arid/arid conditions  
154 across the region, with its annual cycle of brief summer rains and several months of little to no rainfall (McCann,  
155 1999).

156

157 Indigenous African inhabitants to central Namibia, before and during the 19<sup>th</sup> century, would have been familiar  
158 with such seasonal climatic patterns and adapted their lives to best cope with environmental conditions. People  
159 moved around with their livestock or planted and harvested crops at specific localities and times of the year,  
160 thereby navigating the impacts of extreme seasonal hydro-climatic variability or extreme climatic events.

161 While scholars have identified typical hunter-gatherer, agropastoralist and pastoralist groups for precolonial  
162 central Namibia (e.g. Gschwender, 1994/95), such distinctions were not unambiguous. Almost all communities  
163 hunted regularly, farmed and gathered occasionally/episodically, and kept varying numbers of sheep, goats, or  
164 cattle. Furthermore, such communities exchanged goods amongst each other and traded with neighbouring  
165 groups and beyond (Wallace, 2011). Consequently, political and economic dominance was tangible.

166

167 The establishment of permanent missionary and other European settlements in the region from the mid 19<sup>th</sup>  
168 century onwards, altered local power dynamics, and brought about gradual change to some aspects of societal  
169 lifestyles and the environment. It was the missionaries' desire and calling to attract local inhabitants towards  
170 permanent settlement at mission stations in order to not only control and finally convert them, but also to teach  
171 them, among many other things, western agricultural principles that they considered superior to those used  
172 locally. These processes would help fulfil the colonial conquest. Consequently, this gradually changed the 'open  
173 indigenous agricultural economies' to more 'closed agricultural economies' (Ballard, 1986) which became  
174 increasingly dependent on local harvests, grazing and water resources, and employment. Inevitably, as will be  
175 demonstrated, this led to increased vulnerability and social tensions during times of drought. The importance  
176 of cattle as a means of subsistence and wealth increased through the 19<sup>th</sup> and early 20<sup>th</sup> centuries. Grazing  
177 conditions were thus an important attribute to defining the severity of drought by local inhabitants (European  
178 and indigenous). However, we acknowledge that factors such as locust invasions, livestock pressures (e.g.  
179 overgrazing) and fires would also have influenced grazing conditions. Hence, while climate (droughts)  
180 undoubtedly influenced social change, this always requires a critical assessment to avoid the trap of 'climate  
181 determinism' (see Hannaford et al., 2014).

182

183 Arguably the most significant and recurring extreme climatic event affecting central Namibia during the period  
184 1850-1920 was drought. Given the region's strong bimodal rainfall pattern, Europeans writing from the area  
185 during earlier years of settlement, sometimes reported the occurrence of 'drought' during the dry season.  
186 However, as demonstrated, several months without rain during the dry season is 'normal' and thus does not  
187 constitute drought, but rather dry season aridity. It is important to recognize that those reflecting and reporting  
188 on the central Namibian environment and its climate were mostly German missionaries who would have been  
189 accustomed to a much cooler and wetter Germany. Although colonists would have arrived in semi-arid central  
190 Namibia with a likely central-northern European perspective on 'drought', any naivety concerning the local  
191 context would have changed as they became familiar with their new environs and interacted and learnt from  
192 local inhabitants and fellow missionaries who were familiar with the past and contemporary climate. For

193 instance, after an initial four years in central Namibia, missionary Kleinschmidt reports from Rehoboth on 3  
194 October 1846, that this is the ‘*worst*’ time of year with respect to water availability and grazing (i.e. end of the  
195 long dry season). He further comments that there had only been limited rain during the last years and that grass  
196 recovery was only moderate (ARRMS, 1847, 145). Such comments suggest that while Kleinschmidt was  
197 familiar with the cyclic nature of annual rain and dry seasons, perhaps the assessment of there having been  
198 limited rain and moderate grass recovery is one of perspective, still in part influenced from his region of  
199 upbringing in modern day Lübbecke, Germany. Lübbecke has a sub-Atlantic maritime climate with all-year  
200 rainfall and thus grass remains relatively green throughout the year. To this end, and where possible, comments  
201 on weather, climate and the environment require careful scrutiny and comparison across various sources.  
202 However, several missionaries resided and travelled extensively in central Namibia for many years and in some  
203 instances decades (e.g. Viehe: 26yrs; Hahn: 30yrs; Heidmann: 39yrs; Bernsmann: 42yrs; Irle: 47yrs; Diehl:  
204 51yrs), constantly interacting with local community members. In such cases, missionaries developed excellent  
205 knowledge of the local weather patterns and climate, and were able to place contemporary climatic conditions  
206 in perspective, comparing situations with those experienced over many years prior. Two examples follow which  
207 place the severe droughts of 1902 and 1908 in perspective with the worst droughts recalled from the second  
208 half of the 19<sup>th</sup> century:

209

210 “*In the 31 years that missionary Heidmann was in Rehoboth, he had never experienced such a dry year as this*”  
211 [1902] (ARMS, 1902, 20). In addition, “*Missionary Irle, who had been in the region since 1869, could not*  
212 *remember the water table ever having been this low [in 1902]*” (ARMS, 1902, 29).

213

214 “*In the 34 years that missionary Dannert has been here [Omaruru], he can only recall the drought of 1879*  
215 *being as severe as the one felt now [1908]*” (ELCIN, V.23.1, 351).

216

### 217 **3.2 Sub-regional rainfall variability**

218 Strong rainfall gradients occur through central Namibia, both north-south and west-east (Figure 1), which,  
219 together with ‘patchy’ (isolated) rainfall distribution in some years, may at times account for strongly  
220 contrasting sub-regional conditions (Figures 2 & 3). Thus, while most drought events affected the entire region,  
221 there were several instances when one or more areas had ‘sufficient’ or ‘relatively wet’ conditions during a  
222 ‘regional drought’. One or two isolated heavy rain showers in a particular area may have been enough to permit  
223 local stream discharge and rapid grass recovery, while surrounding areas remained parched and dry. For  
224 instance, the rain season failed entirely in Otjimbingue in early 1868 and grazing conditions were in a terrible

225 state, yet some rains fell and streams flowed three times in Omaruru further north, where there was sufficient  
226 grazing, vegetable gardens could be set, and corn be planted (BRM, 1868, 355). Missionary Heidmann reports  
227 from Rehoboth on 27 December 1877 that they had not suffered as much from the drought as those at other  
228 stations across central Namibia. Given that the drought impact at this usually drier locality was not as severe  
229 as that at usually better watered regions, may imply that Rehoboth had rainfall closer to its norm than at other  
230 regions (VEM RMG 2.589 C/i 9, 143). The 1895/6 rain season over most of central Namibia was dry, but  
231 further south (Rehoboth southwards) became critically dry with severe drought conditions. Yet, the usually  
232 much drier western region of Otjimbingue had abundant rain, so much so that “*grass over the new year was so*  
233 *good, as was not seen in many years*” (ZBU, 146, A.VI.A.3, vol. 2). During the severe drought of 1900-03,  
234 conditions were at first also reported to be variable across sub-regions. For instance, towards the end of 1901,  
235 while the much awaited rains had arrived in the northern regions, these were apparently scanty/patchy in the  
236 southern parts (ARRMS, 1902, 24). However, while the end of year (Nov/Dec) instrumental rain records for  
237 1901 indeed show high rainfall in the north (Okahandja: 156% of the norm), they also show slightly above  
238 normal rainfall for central (Windhoek: 110% of norm) and southern (Rehoboth: 115% of norm) station  
239 localities. At other times the documented accounts compare positively with the instrumental records, such as  
240 was the case in 1910, when apparently abundant rains fell at Omaruru (northern study region), “*but in other*  
241 *regions of the land it was not favourable in this regard*” (ELCIN, V.23.1, 375). Instrumental records confirm  
242 this, with Okahandja receiving 110% of the normal rainfall, while western, central and southern regions  
243 (Otjikango, Windhoek, Rehoboth) only received between 75-80% of normal rainfall. However, Gobabis in the  
244 eastern part of central Namibia received 122% of its normal rainfall in 1910. This demonstrates that in addition  
245 to the strong rainfall gradients across the region, there were also disparate rainfall departures from the mean in  
246 a given season or year. In this case, the somewhat wetter regions to the north and east received above normal  
247 rainfall, while the drier regions to the west and south received less than normal rain, consequently exaggerating  
248 rainfall gradients even more.

249

250 Conversely, there were times when most of central Namibia experienced ‘relatively dry’ to ‘near normal’  
251 conditions that would not qualify as a regional drought. In such years, most areas received sufficient rains but  
252 there were instances when sub-regions experienced drought. The year 1890 started variably; in Otjimbingue,  
253 100km south of Omaruru, the rains failed, causing people to disperse (RMG 2.588 C/i 8, 307), yet at Omaruru,  
254 sufficient rain had fallen to permit good grazing conditions, such that people congregated at the station again  
255 (ELKIN, V.23.1, 160). In early 1891, Otjimbingue and Okombahe again had severe drought while reports from  
256 other regions confirmed that good rains had fallen (RMG 2.588 C/i 8, 312).

257

### 258 **3.3 Major droughts in central Namibia (1850-1920)**

259 Please also refer to the work by Grab and Zumthurm (2018) who describe relatively dry and very dry (drought)  
260 years over central Namibia between 1850 and 1900. Our current focus will only be on ‘very dry’ (drought)  
261 years; namely those of 1850-51, 1858-60, 1865-69, 1877-79, 1881-82, 1887-90, 1895-96, 1900-03, 1907-08,  
262 1910-11 and 1912-13. Figure 4 lists the numbers of times ‘drought’ is mentioned in documentary sources each  
263 year. While the depicted results are impacted by documentary data availability, they clearly highlight times  
264 when ‘drought’ received much mention, such as during the major drought events of 1865-69, 1877-79, 1895-  
265 96 and 1900-03. Table 1 lists the reported consequences, concomitant phenomena and human responses during  
266 each of the identified drought periods.

267 One of the first major droughts (1850-51) experienced by missionaries of the RMS resulted in grasslands  
268 becoming degraded and barren, and eventually led to hunger, starvation and death amongst the indigenous  
269 population (Hahn Diaries, 581). Missionaries were particularly distressed that the majority of people left  
270 stations in search of food, and consequently, that very few children attended school (ARRMS, 1850, 21).

271 The failure of two rain seasons (1858-60) carried consequences of widespread hunger, poor harvests, livestock  
272 deaths and missionaries relying on food transported from the Cape colony. Traveler and explorer James  
273 Chapman was in Otjimbingue on 1<sup>st</sup> January 1861 and comments: “*No rain of any consequence has fallen here*  
274 *for 2 years. No grass anywhere, the trees and bushes bare*” (Chapman, 1971, 217).

275

276 The extended drought of 1865-69 ranks as the longest (four consecutive failed rain seasons) over central  
277 Namibia between 1850 and 1920. On 7<sup>th</sup> February 1866, missionary Brincker writes from Otjikango that: “*in*  
278 *this year there is a great drought as is seldom experienced in this land, such that even the Swakop [River] has*  
279 *not yet [7<sup>th</sup> Feb 1866] come down [or reached Okhandja], which otherwise would flow in December at the latest*”  
280 (VEM RMG 2.585 C/i 6, 63). Later it emerged that the Swakop River never reached Otjimbingue for three  
281 years (1866-1868) (Irle, 1906, 22). What made this drought so devastating is the cumulative year-on-year effect  
282 that progressively worsened the situation, leading to widespread hunger, starvation and death of indigenous  
283 people.

284

285 The 1877-79 drought affected most southern African summer rainfall regions (Nash et al., 2019) and coincided  
286 with what has been described as the 1877-78 ‘Global Drought’ and ‘Global Famine’ caused by a major El Niño  
287 (Davis, 2001; Hao et al., 2010; Singh et al., 2018). This was indeed one of the most devastating droughts in  
288 recorded history over central Namibia. This drought, in connection with increasing conflicts that had complex

289 causes, had multiple consequences (Table 1): crop failures, obliterated grasslands, dead trees, lack of wild  
290 foods, social tensions and stock thefts, collapse of commercial enterprises, poverty, starvation and death  
291 amongst people and their livestock. Missionary responses to this drought included dedicated days of prayer and  
292 repentance, and fundraising so that food could be purchased for those in most desperate need. By 1879 the  
293 “conditions in Hereroland [had] not improved, but in the contrary, the longer the worse it [had] become. By far  
294 the main cause of this [was] the endless drought [...] it seems that every now and again such periods return to  
295 southern Africa, where the drought worsens with each year, as is the case with Hereroland now, which finds  
296 itself at the end of a whole number of such years.....” (ARMS, 1879, 19f).

297

298 The situation associated with the 1877-79 drought, in most places repeated itself in 1881/2, largely owing to  
299 the combined effects of drought and war (for a more detailed description see Grab and Zumthurm, 2018). The  
300 drought of 1887-90 was again a lengthy one with similar consequences to those previously. Only the poorest  
301 of people stayed at mission stations, who resorted to begging for food. Others had again spread out and followed  
302 a nomadic lifestyle in search for grazing and water. Large stock losses were reported from mission stations,  
303 while much of the indigenous population remained in a state of poverty and hunger (Table 1).

304

305 The final drought of the 19<sup>th</sup> century to impact central Namibia was due to the failed 1895/96 rain season.  
306 Rainfall records indicate only 48-50% of normal seasonal rains falling over the central and northern regions,  
307 while to the south at Rehoboth only 44% of the norm was measured (Figure 2). According to the Annual Report  
308 of the RMS, “in the entire Southwest Africa there [was] a major drought over most of the year, and in the  
309 southern parts of the country, the so-called Gross-Namalande, it caused total famine. [They] thus had to raise  
310 funds [...] to avoid starvation” (ARRMS, 1896, 14f). Cattle and draught oxen were reportedly in a very weak  
311 state, and to make matters worse, the Rinderpest (cattle plague) had arrived which further decimated stock.

312

313 The period 1900-03 was characterized by three successive below-average rainfall seasons (averaging ~62%,  
314 55% and 60% of the norm respectively for central Namibia) (Figure 2). The impacts were again cumulative  
315 with each year, in particular affecting groundwater and grazing. What made this drought worse still, was the  
316 ongoing Rinderpest (despite vaccines now being used), outbreak of Texasfever among cattle, and repeated  
317 locust invasions which decimated any new grass growth and crops after it had rained a little. The Otjimbingue  
318 1901 station chronicle summarizes the situation after the first of these failed rain seasons: “The drought lasted  
319 until early March [although it continued to be dry thereafter]. The people’s gardens were desiccated without  
320 exception, hunger was great, especially given that no employment was possible at this place. The wells are

321 *drying up and the spring for the mission houses has had no water for many weeks [...] In February we had*  
322 *three rain showers which totalled 59mm. The river came down very weakly for two days, enough to provide*  
323 *some water to the wells. Consequently, it started to green up in the area. But alas, the blazing sun and locusts*  
324 *soon destroyed the greenery. The follow-up rains never came and so the long period of drought continued”*  
325 *(VEM RMG 2.588 C/i 8: 355f.). The extended drought became so bad that it resulted in some mission stations*  
326 *having to close down (something not reported during previous droughts), such as the one at Omandumba*  
327 *(ARRMS, 1903).*

328

329 According to the 1907/08 Annual Report for Southwest Africa, “*The rainfalls were not very productive. In*  
330 *April and May 1907 there were abundant rainfalls so that the grazing and water situation was good. In contrast,*  
331 *rainfall in this last season was well below average. Even though this had less consequence on grazing to the*  
332 *north, the water situation was unfavourable, so that on many farms there were complaints about lack of water*  
333 *even at the beginning of the dry season”* (NAN, ZBU, 155 A.VI.A.3, vol. 17, 232). Overall, central Namibia  
334 only had on average ~69% of its mean rainfall. Some places received near-normal rainfall, and thus did not  
335 suffer drought (e.g. Otjimbingue received 88% of its normal rainfall). Other areas, however, suffered severe  
336 drought conditions, such as Rehoboth (which received only 58% of its normal rainfall) and Omaruru (where  
337 the river never flowed during the rain season and the water situation was dire) (ELCIN, V.23.1, 351).

338

339 The drought of 1910/11 was one of the most severe, affecting all regions of central Namibia. According to the  
340 Annual Report for Gobabis, “*The rainfall season of 1910/11 was very bad. Especially for farming, as the*  
341 *December-January rains were almost entirely absent – only in March was there abundant rain* (Annual Report  
342 for Gobabis, 1910/11, 42f). The instrumental records support this, indicating only 10% (Otjimbingue) to 26%  
343 (Gobabis) of normal Dec/Jan rainfalls across stations. Although some late season (March-May) rains indeed  
344 fell at Gobabis (100% of the norm), all other stations recorded well below normal late season rains (17% at  
345 Otjikango to 44% in Windhoek). This drought carried severe consequences, such as large stock losses (also due  
346 to the Rinderpest), near complete harvest failures, and a desperate shortage of water for human and livestock  
347 needs.

348

349 The drought of 1912-13 was widespread and very severe, as also confirmed by the instrumental rain records  
350 (Figure 2). Since rainfall records began in 1891, this was the driest rainfall season in the south (Rehoboth: 33%  
351 of the norm), 3<sup>rd</sup> driest in the central highlands (Windhoek: 66% of the norm) and 2<sup>nd</sup> driest in the north  
352 (Okahandja: 45% of the norm), and this collectively must rank as one of the most severe droughts since the

353 mid- 19<sup>th</sup> century. Such conditions are confirmed in the Otjimbingue station chronicle for 1913, which  
354 describes the land “*far and wide looking dreary and burnt [by the sun]*”, but that the mountain areas had  
355 received some rain (VEM RMG 2.588 C/i 8, 415). The grazing situation was critical at Otjimbingue, with  
356 apparently “*not a single halm of grass to be seen for many hours distance from the station*” (ARRMS, 1913,  
357 40f), and around Rehoboth in the south where “*even the hunter gatherer communities could not find the*  
358 *essentials to keep themselves alive*” (ARMS, 1913, 14.). The drought was characterized by complete crop  
359 failure in some areas and meagre crop harvests in others, widespread drying up of wells, and depleted grazing,  
360 such that farmers were preparing to vacate their land.

361

#### 362 **4. Discussion**

363

364 What follows is a discussion on how missionaries perceived and experienced droughts and their consequences  
365 through the time-period 1850-1920. Sub-periods of time are unpacked and characterized according to the most  
366 notable and written about impacts. This does not suggest a rigid linear development of drought impacts and  
367 responses through time, and neither do we imply that one particular impact was restricted to a given sub-period.  
368 Rather, the intention is to demonstrate that the impacts, consequences, responses and perceptions of drought  
369 during this historical period were not static through time.

370

#### 371 **4.1 Drought during the 1850s: from famine to societal dispersal**

372

373 Missionary Hahn, stationed at Otjikango, reports the first drought-induced famine during spring 1851. First  
374 reports of deaths from starvation date from September 1851, and on 19 October Hahn wrote in his diary that  
375 the “*misery is enormous. Almost daily you see new pitiful creatures arrive at the station. They drag themselves*  
376 *over here to get some food. Our help is not enough at all*” (Hahn Diaries, 515.). On 9 November 1851, Hahn  
377 noted that several children had died and that the hardships were severe owing to terrible drought. By mid-  
378 December he observed that there were more victims of drought and hunger and that not even a third of the  
379 missionary station inhabitants remained, but that people had scattered into the ‘veld’ (open country) where they  
380 were in search of wild berries and roots. It was only towards the end of December 1851 when rains finally  
381 arrived, but these were too late to avoid further hunger and starvation. From Rehoboth, missionary Kleinschmidt  
382 expressed concern at the absence of many children from school due to drought and the dispersal of people.  
383 During 1850, some 180 pupils attended classes, but dwindled to only 70 learners by April 1851 (ARRMS, 1851,  
384 23). On 22 June 1852, missionary Rath wrote from Otjimbingue that “*the people who remain are parched by*

385 *hunger and stray around like hungry wolves. You cannot do anything with such people anywhere in the world,*  
386 *least of all among pagans. The needs of the stomach overshadow everything else” (VEM RMG 2.588 C/i 8,*  
387 *36).*

388

389 The tension for missionaries during this time was that while their calling was to attract people to the stations  
390 for evangelistic and educational purposes, they did not have the capacity to feed local inhabitants during times  
391 of drought and crop failure. Hence, people resorting to hunting and gathering during such times, which meant  
392 dispersal of the population, and mission stations being deserted. During these earlier years, the missionaries  
393 themselves were in dire need of food and lacked any institutional supporting structure to assist them during  
394 times of severe food shortages. For instance, when missionary Hahn travelled past Rehoboth station on his way  
395 to Cape Town in 1859, he was shocked that missionary Kleinschmidt and his family could only drink goats’  
396 milk and depended on food they received from travellers. Their cattle were too malnourished to provide milk  
397 or meat (ARRMS, 1859, 34). Population dispersal and movement as a local drought/famine coping mechanism  
398 would not have been a new thing and was a typical/logical response that would continue into later decades  
399 (Table 1).

400

#### 401 **4.2 Drought during the 1860s: from dispersal to societal tension**

402

403 Drought during the 1860s intensified and that of 1865-1869 was one of the longest and most devastating during  
404 recent historical times (Grab and Zumthurn, 2018). During this great drought, missionary stations were again  
405 vacated, as even missionaries and colonists themselves were forced to abandon the stations. For instance,  
406 economist Redecker departed Otjimbingue with some of the converts to relocate where surface or ground water  
407 was still available along the Omaruru River (VEM RMG 2.588 C/i 8, 199). Others that remained at their station  
408 (e.g. missionary Viehe, see below) felt that they had been abandoned and left in need by the absence of all those  
409 who had left. Brincker reported from Otjikango on 10 September 1869 that “*the drought and in its wake the*  
410 *famine is pushing very hard on us and many poor people have died of starvation. Indeed, it was told here, that*  
411 *the hunger among the Ovatjimba or the poor Herero is so large that they resorted to cannibalism, which most*  
412 *likely is exaggerated” (VEM RMG 2.588 C/i 8, 70). This is the only account which hints of cannibalism in all  
413 the documents analysed, the reality of which even the missionaries doubted. It thus serves to emphasise the  
414 seriousness with which the situation was viewed. In desperation, missionary Brincker also departed Otjikango  
415 station and moved to Otjimbingue where missionary Hahn was stationed. Here too, there were only a few men  
416 with their families who remained. Despite the shortage of food, Hahn claims that he was left with little choice*

417 but to feed some hundred children from money provided by the missionary society (BRM 1869, 262f). While  
418 there had been some improved institutional financial support from Germany by the late 1860s, such support  
419 seemed insufficient to benefit the needs of those residing at stations.

420

421 Missionaries usually demonstrated sympathy towards their communities and the nomadic habits of their people.  
422 Although missionaries expressed a deep understanding of the tensions and needs faced by the local population,  
423 their descriptions began to portray an undertone of disdain towards what was considered ‘unChristian-like’  
424 behaviour. For instance, in May 1868, missionary Viehe complained from Otjimbingue that most of the  
425 residents were away and would thus not be able to care for him and his family, and writes: “*but who can take*  
426 *this amiss for a pagan people?*”(BRM, 1868, 247). Drought seemed to regularly interrupt the core purposes of  
427 the RMS in central Namibia, as is reflected by missionary Brincker from Otjikango towards the end of the long  
428 drought (August 1872):

429 “*There is one thing that worries me, although an earthly one, it is the drought that is increasing each year.*  
430 *What should become of our communities if they cannot settle down and hence consolidate? Admittedly, we*  
431 *cannot complain about the roving of our community members, but the question arises if it is possible at all to*  
432 *implement culture under such unfavourable circumstances. The nature of this country treats these poor people*  
433 *more than uncharitably*” (BRM, 1882, 234f).

434

435 Drought during the late 1860s was accompanied by armed conflicts, which seemed to have escalated with time.  
436 Hence, human movement to and from mission stations was no longer only a consequence of drought but also  
437 due to conflict. Missionaries were well aware of this, so that in the annual report of 1869, war was identified  
438 as the primary reason for the scattering of residents from Otjimbingue. The editor added: “*we hope for peace*  
439 *and rain so that the bulk of the blacks can move onto the station again and our missionaries are saved and full*  
440 *of work again*” (ARRMS, 1869, 24). Missionary Heidmann, who had just re-opened the station at Rehoboth in  
441 1871, acknowledged that it was not only the long drought and associated general scattering of people, but also  
442 the “*endless clan feuds and plundering raids*” that were responsible for the impoverishment of the once wealthy  
443 community (BRM, 1871, 129). However, drought and conflict cannot be separated in such circumstances as it  
444 was the scarcity of grazing resources, death of livestock, hunger and starvation due to drought, that essentially  
445 lead to many of the conflicts, wars and livestock thefts. These were also connected to increasing trading  
446 activities and wealth accumulation in the form of cattle (Henrichsen, 2011; Wallace, 2011).

447

448

#### 449        **4.3 Drought during the 1870s: from societal tension to environmental deterioration**

450        The effects of armed conflicts became even more pronounced during the drought of the late 1870s, a particularly  
451        severe dry period which affected most of southern Africa (see Nash et al., 2019). To make matters worse for  
452        the missionary vision was that the exodus from stations continued during periods of drought. The year 1877  
453        was not an easy one for central Namibia (known as Hereroland at this time): “*firstly there was a long drought*  
454        *with famine*”, and secondly because of “*a strained relationship between the Herero [indigenous people group]*  
455        *and British colonists*”. In addition, the Namaqua [another indigenous people group] had to deal with their loss  
456        of power. Collectively, these factors triggered conflict, which, “*together with the consequences of drought*  
457        *increased distress and want even more*” (ARRMS, 1877, 19f).

458

459        In 1877, William Coates Palgrave was sent as a special commissioner from the Cape to investigate whether  
460        Namibia had potential to become a valuable British colony. He commented on the extensive drought after  
461        arriving at Walvis Bay on 12<sup>th</sup> October 1877: “*The drought which has so seriously affected the Colony has also*  
462        *been severly felt in this country and Great Namaqualand, particularly by those who are wholly or in part*  
463        *dependant on the wild products of the earth for their subsistence. Many of those are starving and stock-lifting*  
464        *has become unusually prevalent and has given use to much bad feeling between the tribes*” (CAD, NA 286).  
465        Many contemporary observers noted that the Herero's cattle had rapidly multiplied over the years. They moved  
466        southwards in search of new pastures due to drought in northern Namibia, although political motives also played  
467        a role (Henrichsen, 2011). Missionary Heider from the southernmost station of the study area, Hoachanas, wrote  
468        in 1877 that the complete Nama community was forced to leave the station due to the Herero pushing into the  
469        region with large herds of cattle (ARRMS, 1877, 31). Missionary Büttner, who had spent seven years at  
470        Otjimbingue, predicted in the same year that the expansion of the Herero would force the Nama and Damara to  
471        become “*violent thieves*” (BRM, 1878, 11). A year later (1878), it was estimated that some £800 worth of stock  
472        had been stolen over a 6-month period in the immediate surrounds of Rehoboth (VEM RMG 2.588 C/i 8, 247).

473

474        Due to a seemingly endless drought and armed conflict, conditions in Hereroland progressively worsened  
475        through the period 1877-79. The impression was that due to multiple drought years, conditions had worsened  
476        with each year in an accumulative manner, such that inhabitants suffered greatly. So much so, that this led to  
477        much conflict between white settlers and the indigenous Herero over want for the little grazing still available.  
478        Conflicts also arose between the Herero and Namaqua, as also between English border patrols and those moving  
479        their herds (ARRMS, 1879). In addition, the impression from missionaries was that drought had so much  
480        reduced wild foods (bulbs, roots, berries, game and “*creeping things*”) that the Damara (mostly hunter-gatherer

481 communities) were forced to steal livestock to stay alive. Missionary Bernsmann from Otjimbingue, for  
482 example, wrote in 1878 that the Herero cast out the Nama and the Damara from their places and that “*there was*  
483 *only very little food to gather in the fields and [that] the game [had] escaped to places out of reach where they*  
484 *would still find good pastures. What choice other than stealing do they have?*” (VEM RMG 2.588 C/i 8, 247).  
485 This led to campaigns between the Damara and Herero, with “bloody consequences”. The views of the German  
486 missionaries was, however, that the situation would not have been as bad had it not been for the English  
487 governments’ plans to colonize Hereroland (ARRMS, 1879, 19f). They were, nevertheless, also very critical of  
488 the indigenous population for what was perceived to be overstocking. On 13<sup>th</sup> March 1879 missionary Büttner  
489 makes a written complaint to the local inhabitants near Otjikango: “*...in earlier times when you had less*  
490 *livestock you could stay at one place, and I remember in times of past drought how the church and school was*  
491 *full. Now that you are wealthy [with livestock] you always complain of hunger and avoid coming to the station*”  
492 (BRM, 1879, 302).

493

494 Notably, German missionaries gave the Damara considerably more attention during the drought of the late  
495 1870s than during that of the preceding decade. Several missionaries emphasised the particularly hard fate of  
496 these people. Due to the failure of rains and more intensive hunting of wild animals and gathering of edible  
497 plants, it was the widespread impression that such *wild food* products became increasingly scarce. Similar  
498 observations (i.e. disappearance of wild foods after drought events) were reported from the Kuruman region of  
499 the Kalahari during the 1850s, where the environment and settlement history is similar to that of central Namibia  
500 (Jacobs, 2002). At this stage, and continuing into the early 1880s, the entire German missionary cause in central  
501 Namibia seemed to have disintegrated and required new approaches given the constant coming and going of  
502 local people, in response to war and drought. Missionary Brincker writes from Otjimbingue (1882): “*There*  
503 *are two extremely obstructive enemies to our work here, namely war and drought. [...] Our people have*  
504 *received a wretched land for their inheritance, in which no culture is possible. Christianity must take on a new*  
505 *form, it must nomadize, which has probably not yet been sufficiently understood and considered*” (BRM, 1882).  
506 Missionaries at various stations responded with a declaration to commit one hour of prayer for rain, twice  
507 monthly.

508

509 Rapid environmental deterioration during the 1870s not only constituted the depletion of wild edible plants and  
510 fauna, but also groundwater resources. Missionaries, colonists and indigenous peoples relied heavily on  
511 perennial springs, and particularly so through the long dry seasons. Although unsustainable water extraction  
512 and harvesting of wild foods is already alluded to in the 1860s, such accounts become much more prominent

513 during the 1870s and subsequent decades of colonialism. On 11<sup>th</sup> October 1860, missionary Rath arrives at  
514 Tsaobis station and comments that this place formerly had a spring that never dried up. He laments that the  
515 nonsensical economy of the whites resulted in “*not a drop of water to be found there anymore*” (VEM RMG  
516 2.588 C/i 8, 117). A decade later (September 1871), missionary Hahn writes from Ameib, reflecting that in  
517 past years, water in abundance had occurred there and in the Erongo Mountains, but that given the severe  
518 droughts over the past years, there had been dramatic disappearance of springs. However, he also blames the  
519 Namaqua people for the general environmental destruction, particularly the deforestation of shade bearing  
520 mimosas (VEM RMG 1.577 a B/c II 3, 451). By late February 1877, missionary Dannert at Otjimbingue noted  
521 that the spring, which usually had running water throughout the year, had dried up. Water was only available  
522 at a depth of seven feet. Earlier there were rows of poplars growing in front of the mission house at Otjimbingue,  
523 but these, as most of the fruit trees planted by missionary Hörnemann, had perished by 1877 owing to drought  
524 (RMG 2.588 C/i 8, 242f). Otjimbingue, Omaruru, Omburo, and other mission stations had ‘permanent’ springs  
525 in their riverbeds, from where water flowed onwards for at least an hour’s walk during the entire year. However,  
526 by 1879, such spring water had dried up considerably, or even disappeared in some cases. Consequently, one  
527 now had to dig wells in the Otjimbingue and Omaruru streambeds, while the spring at Omburo only flowed  
528 over half its former distance (ELCIN, V.23.1, 63).

529

#### 530 **4.4 Drought during the colonial era (1880s-1920): capitalism and further environmental deterioration**

531 Gradually, during the 1870s, opportunities for wage labour expanded more rapidly. The first mention of wage  
532 labor comes from missionary Böhm stationed at Ameib in 1873: “*Hunger and poverty belong to the lives of the*  
533 *Namaqua, but one can sense that the desperation is no longer as severe as in previous years. Most of these*  
534 *people, apart from during short hunting campaigns, tend to stay at the station even during dry times. The men*  
535 *earn much through ostrich hunting and last year made plentiful tobacco, a portion of which they sell*” (ARRMS  
536 1873, 37). The increasing dependence on wages had positive and negative consequences for the ability of  
537 indigenous inhabitants to acquire food. However, their resilience towards drought did not noticeably increase.

538

539 One of the most important new modes of earning a living for people connected to missions was the so-called  
540 *Frachtfahren*, which involved the transporting of goods by ox-wagon (ELCIN, V.23.1, 51). However,  
541 *Frachtfahren* was interrupted in 1878 due to drought (lack of water and food for draught oxen) – this had serious  
542 implications for those reliant on wage labor. As commerce increased, many new drivers were required by the  
543 1890s. The head of the Otjimbingue district reported in 1897, that while indigenous people had extensively  
544 cultivated crops in riverbeds in earlier years, this practice had receded in importance given that considerable

545 money could be earned through *Frachtfahren*. Consequently, it was more attractive for drivers to earn a living  
546 and buy food, rather than to produce it themselves (NAN, ZBU, 147, A.VI.A.3, vol.2a., 142). This practice was  
547 not without its problems, especially after the Rinderpest (infectious disease of ruminants). People had lost their  
548 livestock during the outbreak and were now forced to buy goods or new oxen on credit. During the 1900-1903  
549 drought, there were several accounts of people not having enough food in Rehoboth, Omaruru and Otjimbingue  
550 given the fact that income opportunities from *Frachtfahren* had declined, also due to drought (ELCIN, V.23.1,  
551 245; ARRMS, 1901, 24; VEM, RMG 2.588 C/i 8, 355f). For 10-11 months the drought was so severe that the  
552 *Frachtfahren* closed down almost entirely, and where it continued, it was at ‘great loss’ (assumably loss of  
553 draught animals) (ARRMS, 1903). At the time, it proved difficult to find an alternative way to obtain food.  
554 Prices were exceptionally high in times of drought, wild foods were now increasingly scarce to find, and wage  
555 labourers generally did not cultivate crops themselves. One possibility for supplementary wages during times  
556 of drought was to work on the railways or in the mines for a meagre salary (ARRMS, 1911, 35; ELCIN, V.23.1,  
557 252). In Otjosazu, the harvests of 1901 largely failed, resulting in substantail hunger amongst poor people who,  
558 unlike the more financially privileged, were unable to purchase food to replace what they had lost through the  
559 bad harvest (ARRMS, 1901, 29).

560

561 A new form of relief for mission communities during the 1900-1903 drought was financial or material support  
562 from the colonial government. The RMS mentions in its 1902 annual report that the impact of drought was felt  
563 as severely as ever. The RMS thanked settlers and, in particular, the German government for their support,  
564 through which stations had apparently received not only drought relief money and food aid, but also financial  
565 assistance for much needed infrastructural developments and renovations, which could improve future drought  
566 coping mechanisms (ARRMS, 1902, 20). For example, the station of Hoachanas received food worth 1000  
567 Mark from the German state, which, in addition, financed the construction of 22 wells (ARRMS, 1902, 20).  
568 The first reported construction of a sand dam/water reservoir is mentioned in the 1901/02 Annual Report for the  
569 Windhoek district (p228). Water in this reservoir had apparently reached a depth of 3½ m in 1902 and  
570 demonstrates a first major infrastructural and long-term water management initiative. It is doubtful, however,  
571 that such government aid had any far-reaching positive effects as many people were still forced to find wild  
572 food products during times of desperation and the general decline of human health was widely reported during  
573 the first decade of the 20<sup>th</sup> century. The official German Annual Report for the colony of South-West Africa  
574 (1911/12) announced that “*the lack of fresh milk, on which locals have depended as staple food for generations,*  
575 *plus the scarceness of field crops, which were the only available fresh vegetables for locals after the drought*  
576 *of 1911, can be regarded as the main reason for the many cases of scurvy”* (NAN, ZBU, 161, A.VI.A.6, vol 1,

577 16f).

578

#### 579 **4.4.1 Impacts on vegetation cover**

580

581 Degradation of vegetation during times of drought seems to have been spatially patchy, largely owing to  
582 anthropogenic factors. Grass and shrubs were heavily grazed around mission stations and settlements where  
583 some water was still available (through springs, wells), as also along the transport routes. There are thus  
584 accounts of livestock deaths along transport routes for lack of grazing, such as was the case during the drought  
585 of 1877-79. On his journey from Ameib to Walfish Bay in March 1878, missionary Böhm described that there  
586 was no grass to be seen along the route, and even less so at watering points and grazing posts. He observed  
587 oxen from many other people on their way to collect goods from the ship (at Walfish Bay), but that many of  
588 these had died as they were too starved and weak – many lost more than half their outspan (BRM, 1878, 206).  
589 As also mentioned by Grab and Zumthurm (2018), drought and war forced the Herero to keep their livestock  
590 close to Omaruru during the 1880-82 drought. Consequently, not only was grass cover completely depleted,  
591 but even grass roots were damaged due to trampling. This would have had longer-term consequences for  
592 vegetation recovery even when the rains returned. Once the situation had become more peaceful, livestock  
593 could be taken to more remote outposts where there was still sufficient grazing (ELCIN, V.23.1, 101). Similar  
594 accounts came from other stations during droughts and dry periods of the late 19<sup>th</sup> century, in part, also due to  
595 the substantial growth in livestock numbers. Missionary Diehl reports from Okahandja in September 1886 that  
596 grazing was so heavily depleted around the station that even soon after the end of the rainy season there was no  
597 grazing to be found in a wide area around the post (BRM, 1887, 75).

598

599 Such situations described above would further worsen as livestock numbers continued to increase and severe  
600 droughts return in later years. At the same time, trading intensified and more and more goods were transported.  
601 On arrival of the 1895-96 drought, authorities had realized that both the decimated vegetation and its associated  
602 risks to draught animals along the northern transport route and its outposts via Otjimbingue, required some  
603 intervention (long-term coping/adaptation mechanism). Thus, plans were made for an alternative more  
604 southerly transport route, via Rehoboth:

605 *“With the start of the new year [1895] the heat intensified, and as a consequence also the drought. Often the*  
606 *clouds accumulated and promised much rain, but the westwind blew them away. The desperation increases,*  
607 *people and livestock suffer. The Frachtfahrer are afraid to journey to the Bay because their losses increase*  
608 *from week to week [.....] From Swakopmund and the Bay, there have been some 880 freight items delivered*

609 *into the hinterland in one year, of which over 500 were transported via Otjimbingue. Some 10 000 to 12 000*  
610 *oxen as draught animals came over Otjimbingue this past year, where they would spend several days to rest,*  
611 *feed and recover, but at the same time decimated the grazing. The troops have thus started building an*  
612 *alternative rout via the Kuiseb River from the Bay to Rehoboth, and thereby relieve the pressure on the main*  
613 *route from the coast to Windhoek” (VEM RMG 2.588 C/I: 8).*

614

#### 615 **4.4.2 Impacts on groundwater**

616

617 Drought at the beginning of the 20<sup>th</sup> century had serious impact on groundwater availability across central  
618 Namibia and wells drying up were widely reported, much more so than during previous droughts (Table 1). For  
619 instance, the well at the missionary house at Otjimbingue, completely dried up in March 1901, preventing the  
620 planting of crops (VEM, RMG 2.588 C/i 8, 355f). The missionary well at Omaruru, which “*always had water*  
621 *in abundance*”, had to be deepened in 1901 (ELCIN, V.23.1, 252). The drought of 1901 was similar in  
622 magnitude (i.e. rainfall quantity) to the drought of 1896 in most areas (Figure 3). This suggests that increasing  
623 water demands and its associated groundwater extraction may have contributed to the faster depletion of  
624 groundwater in 1901, and hence the necessity to go deeper. Accounts of springs/wells drying up became  
625 frequent during the colonial period, even during 1903/04 when rainfall had improved slightly in some districts  
626 (NAN, ZBU, 151, A.VI.A.3, vol.10, 102; Annual Report 1903/04, Windhoek). After another dry rain season  
627 (1907/08), the head of Windhoek district reported that numerous wells were dry (NAN, ZBU, 156 A.VI.A.3,  
628 vol. 19, 3). Although wells were deepened at Omaruru in 1907, the following year, missionary Dannert had to  
629 dig even deeper to reach water required for domestic purposes. The situation worsened during the drought of  
630 1910/11, forcing the colonial government to increase drilling activities and go deeper still. In early 1911, the  
631 great well at Otjimbingue, which was by now operated using a wind-engine, had dried up for the first time since  
632 its construction 35 years earlier. The stations first Herero Christian convert, Johanna Gertse (75 years of age)  
633 could not remember the water-level ever being that low (VEM RMG 2.588 C/i 8, 405). Such accounts further  
634 suggest rapid groundwater depletion during the early 20<sup>th</sup> century due to recurring droughts and greater water  
635 extraction driven by both water demand and improved ability to do so. In response to the severe drought of  
636 1910 and associated state of emergency on farms, the German colonial government committed itself to drilling  
637 operations on private farms. However, given such a low water table, drilling was required to much greater  
638 depths than during previous dry periods, in some cases to depths of 40-50m (NAN, ZBU, 159, A.VI.A.3, vol.  
639 24. 85f). Reports in 1911 emerged from many districts that blasting and drilling operations were being  
640 undertaken in desperation to reach groundwater. For instance, in Otjikaru drilling was required to 38m depth,

641 but even so ‘only’ provided 250 litres per hour (ARRMS, 1911, 37).

642

643 While technological advancements during the first decade of the 20<sup>th</sup> century permitted water extraction from  
644 greater depths, and served as both an immediate drought coping and longer-term drought adaptation  
645 mechanism, this surely had negative implications for future groundwater resources, water supply and  
646 ecosystems. During the severe drought of 1910/11, apparently “*hundreds of large and strong trees along the*  
647 *Omusena River perished for lack of water*” (VEM RMG 2.588 C/i 8, 405f). During recent times, similar  
648 concerns have been expressed for riparian vegetation along Namibia’s ephemeral rivers, where water  
649 availability is erratic and sensitive to water abstraction and the construction of dams in upper catchments  
650 (Jacobson et al., 1995; Jacobson and Jacobson, 2013; Arnold et al., 2016). We thus pose the question whether  
651 this early ecological disaster (possibly the first reported in central Namibia) was due only to the exceptional  
652 drought, or a combination of drought and deep-water extraction associated with increased water demand?

653

## 654 5. Conclusions

655

656 This study has highlighted historical drought events in semi-arid central Namibia between 1850 and 1920. Early  
657 instrumental rainfall records (1891-1913) used in this study aid to quantify the hydro-meteorological severity  
658 of some of the identified drought events. These further demonstrate the confined period of summer rainfall  
659 (Dec-April) and the natural annual cycle of several months of negligible rainfall, constituting aridity rather than  
660 drought. Such instrumental rainfall records are valuable to quantify drier/wetter years, and the extent, duration  
661 and severity of droughts. However, determining the *real* impact of historical hydro-meteorological droughts  
662 depends largely on available documentary sources which report on environmental and human consequences  
663 and associated responses. To this end, the central Namibia historical drought context, within the given temporal  
664 and spatial context of this study, presents some important key findings:

- 665 1. The severity of historical drought impacts over central Namibia, during some drought events, were  
666 spatially strongly contrasting. This is given the extreme west-east and north-south rainfall gradients;  
667 hence percentage rainfall departures from the norm can be highly variable across the region during a  
668 given drought event. Consequently, place-based natural environmental and anthropogenic consequences  
669 and responses would differ markedly in magnitude during some drought events, as would reporting on  
670 the event.
- 671 2. Consequences of drought in a semi-arid environment with strongly seasonal rainfall are potentially far  
672 more catastrophic than drought events in regions with rainfall distributed throughout much of the year.

673 This is due to the cumulative impact that a failed rain season has upon the subsequent long (~ 6 month)  
674 dry season. Our study also identifies multiple consecutive failed rain seasons (e.g. 1865-1869) that not  
675 only led to uninterrupted drought over several years, but also a year-on-year cumulative drought impact.  
676 3. Human experience and associated reporting of drought events depends strongly on social,  
677 environmental, spatial and societal developmental situations and perspectives. For instance, drought in  
678 this study is reported mostly from missionaries who were strategically positioned within the broader  
679 landscape (i.e. next to springs, episodically flowing rivers). Missionaries were relatively immobile given  
680 their career and societal calling. This would have been in direct contrast with the indigenous people  
681 groups, who led a highly mobile lifestyle across the entire region and beyond – although such mobility  
682 decreased through time and had dire consequences in later years (social tensions, conflicts, lowered  
683 coping mechanism to drought). As populations and livestock numbers grew, these resulted in  
684 overstocking (and overgrazing, excessive trampling) in specific spatial contexts with low carrying  
685 capacity during later years. Hence, the perceived impacts of droughts in later years would have also  
686 been a product of human engineered circumstances. In later years, increased water abstraction (lowering  
687 water tables), holding back river flow through reservoir constructions, the ability to more easily acquire  
688 imported foods, opportunities for employment and improved travel, would have collectively changed  
689 the dynamics and experiences of a given drought event. In addition, ‘external’ factors that were rare or  
690 unknown in earlier decades of the study period, but which became more prominent in later years (e.g.  
691 locusts plagues, Rinderpest, increased occurrence of fires) impacted human and livestock resilience,  
692 and thus perceived impacts of drought. To this end, it is imperative to evaluate historical drought events,  
693 not only according to meteorological parameters, but also in consideration of changing natural-  
694 environmental and human-environmental contexts through time. For this, written-documentary sources  
695 are an essential and invaluable proxy record.

696  
697 **Data availability.** The sources of all original data are quoted in the manuscript.

698

699 **Author contribution.** TZ collected all the documentary data. SG and TZ analysed records and wrote the paper.  
700 SG produced all the Figures.

701

702 **Acknowledgements.** TZ received research funding from the Fritz Sarasin Stiftung in Basel and a  
703 "Differenzstipendium" from the University of Basel, for which we are most thankful.

**Notes**  
 1. Livestock deaths during droughts between 1895 and 1913 are due to the combined impacts of the cattle plague (Rinderpest) and drought  
 2. Population dispersal during some drought events was also due to social tensions/war  
 3. Low school attendance was at times due to the combined factors of drought and social tensions/war  
 4. Drought variably (directly or indirectly) caused social tensions and theft (i.e. as either a primary or secondary causative factor)  
 5. Indigenous rain making is only referred to during the 1865-69 drought in our documentary records - this does not imply that the practice was absent during other drought events
